THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXIII.

FROM MAY 10, 1889, TO NOVEMBER 1, 1889.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at "THE ELECTRICIAN" Offices, 1, Salisbury-court, Fleet-street, E.C.

1889.

Digitized by Google

17913

INDEX TO "THE ELECTRICIAN."

VOL. XXIII.

General Alphabetical Index.

***Italic* figures denote that the subject matter is in the "Editorial Notes" or in the "Foreign Correspondence."**

A B C of Electricity, The, *592*, 613.
Aberdeen, 444, 541, *593*.
Accumulator, The Schoop, 187.
Accumulators as the Main Source of Supply, Distribution of Electricity in Chelsea, &c., with. By Major-General Webber, C.B. 577, 597, 624.
Accumulators at the Paris Exhibiton, 594, 634.
Acheson's Calelectric Generator, *395*, 406.
Africa, The East Coast of, The Telegraph on, 396.
Africa, The West Coast of, Cable, 137.
Agricultural Engineers, The Association of, of Great Britain, and the Paris Exhibition, 55.
Ahern and Company, United Telephone Company *v.*, 221
Air, Electrification of, by Combustion, 500.
Airdrie and Coatbridge, 264, 343, 487, 566.
Alioth Arc Lamp, The, *398*.
Alioth et Cie., MM., The Exhibit of, 397.
Alloys, Iron and Nickel, Magnetic Properties of, 279.
Alloys, Non-Magnetisable, 420.
Alternate-Current Apparatus, The Brush, 290, *302*.
Alternate-Current Dynamo, The Elwell-Parker, 44.
Alternate-Current Experiments, Mr. Preece's, 486.
Alternate-Current Experiments with Armoured Cables, *640*.
Alternate-Current Motors, 141.
Alternate-Current Motor, M. Leblanc's, 357.
Alternate-Current Motor, The Patten, *539*, *559*, 572, 634.
Alternate-Current Transformer, The, Dr. Fleming on, *395*.
Alternate-Current Waves, Visual Reproduction of, 137.
Alternate-Current Working, by W. M. Mordey, *51*, 64, 94, *108*, 120, 324, 326, *367*, *368*, 388, *394*, *417*.
Alternate-Current Working, Mr. Atkinson on, *394*
Alternate-Current Working, Mr. Swinburne on, *367*, *417*.
Alternate Currents, Resistance Coils for Use with, 110.
Alternate Currents, The Terminology of, *155*; Sir W. Thomson, 154.
Alternating-Current Circuits, Laboratory Notes on. Prof. W. E. Ayrton, F.R.S., and John Perry, F.R.S., *186*, 192, *211*, 217.
Alternating-Current Motors, Self-Induction in: Jas. Swinburne, 154.
Alternating-Current Motors, the Ganz, Mr. Nikola Tesla on, 114.
Alternating Currents, On the Distribution of Energy by Means of. By M. Leblanc, 320, 346, 372, 398, 508.
Alternating Currents, The Choice of Cables for, 654.
Alternating Motor, The Ganz, 18.
Alternating Motors, 359, 436, 437.
Alternating System, Progress of the, in America, *42*.
Alternating System, The Ganz, 16.

Alternators—
The Dandeu and Naze, *463*.
The Kapp, 425.
Mordey Fifty Horse-Power, 346, 353.
The Thomson-Houston, *373*.
Alternators, The Theory of, 413, 459.
Altona, 487.
Aluminium Process, The Hall, *559*.
Aluminium Process, The Héroult, in Germany, 18.
Amalgamation of the Telephone Companies, 88, 120, 169.
Amalgams, Electromotive Force of, 214.
America and Submarine Cables, 246.
American Association for the Advancement of Science, The, *508*.
American "Ball" Electric Lighting Company, The, in Paris, 293.
American Bell Telephone Company, The, *154*, *534*.
American Engineers, The, at the Subway and at Deptford, 161.
American Engineers, The Visit of, 82.
American Institute of Electrical Engineers, The, Meeting of, *126*, *160*.
American Street-Railway Association, Meeting of the, *611*.

Ammeters—
Blyth Current-Weigher, The, 485, 549.
Edison Dead-Beat Galvanometer, The, *446*.
K.M.R. Pocket Galvanometer, The, 389.
Portable Pocket, 438.
Richard Registering Central Station Instruments, The, 652.
Ammeters and Voltmeters, Portable Pocket, 438.
Anglo-American Brush Corporation, King, Brown, and Co. *v.*, 53, 91, 116, 200.
Anglo-American Brush Corporation, Mr. Lane Fox and the, 389.
Apparatus, Standard Types of, 297.
Arbroath, 291, 370, 488.

Arc Lamps—
Alioth, The, *398*.
Brown, The, *271*.
Hauck, The, 460.
Kremenetsky, The, 560.
Pieper Semi-Incandescent, The, 318
Poege, The, 169.

Arc Lamps (*continued*)—
Simple, 44.
Thury, The, *270*.
Wenzel, The, 481.
Zipernowsky, The, 661.
Arc Light Carbons, Life of, 420.
Arc Light Photometry, 370.
Arc Lighting, The Profits of, *458*.
Architects' Association, Soirée of the, 53.
Argentine Telegraphs, The, 110.
"Armature Re-action" Type, Elementary Theory of the. By W. M. Rechniewski, 141.
Armoured Cables, Alternate-Current Experiments with, *640*.
Asbestos Reef in Griqualand West, 515.
Asbury Park (N.J.), Electric Railroad at, *180*.
Assay, Electrolytic, of Copper, 54.
Athens, 567.
Atherton, 317.
ATKINSON, L. B.
The Theory of Alternators, 413.
The Use of the Integraph in Determining some Problems in Electro-Dynamics, 23.
Atkinson's Work on "Electric Lighting" 100
Atlantic Cable Combination, The Reported, 318.
Atmospheric Electricity, 318.
Australia, Electric Lighting in, 290, 540.
Australia, Electric Tramways in, 292.
Australia, The Telephone in, 515.
Austria, Electric Lighting Progress in, *181*.
Austria, The Electrical Transmission of Power in, *136*.
Automatic Expansion Gear for Electric Light Engines, 634.
Automatic Principle, An Electric Reading Lamp on the, 371.
Automatic Regulator, The Thury, *269*.
Automatic Safety Apparatus, The Brown, *271*.
Automatic Sprinkler, The Shaffer, and Fire Alarm, 515.
Awards, The Birmingham Exhibition, 623, 660.
Awards, The Paris Exhibition, *539*, 551, *566*, 593, 642.
Ayr, 246, 369.
AYRTON, Prof. W. E., F.R.S.
The Practical Unit of Induction, *169*, 633.
AYRTON, Prof. W. E., F.R.S., and JOHN PERRY, F.R.S.
Laboratory Notes on Alternating Circuits, 192, 219.
Bacup, 317, 465, 567.
Ball and Point, The Effect of Placing a, in a High-Tension Alternating-Current Circuit, 421.
"Ball," The American, Electric Lighting Company in Paris, 293.
Ballymony, 81.
Bangkok, 566.
Bangor, Municipal Electric Lighting at, 257.
Bank of England, Electric Motors at the, 161.
Bank Lighting, 82.
Bankruptcy, 461.
Banquet to the Members of the Paris Congress, 470.
Bare Conductors, The Use of, *565*.
Barker Storage Battery, The, *559*.
Barmen, 188, 213.
Barnet, 4, 83, 189, 567.
Barnsley, 265, 467, 515.
Baroda, 443.
Barry, 264.
Bath, 81, 137, 240.
Bath Electric Light Station, The, 655.

Batteries, Primary—
An Improvement in, 642.
Delany's Gravity, *358*.
Germain Dry, The, 292.
Renard, The, 466.
Weymersch, The, 203.

Batteries, Secondary—
Barker Storage, The, *559*.
Knowles Storage Cell Plate, The, 388.
New Storage, A, for Tramway Work, 595.
Schoop Accumulator, The, 187.
Woodward Storage, The, 53.
Batteries, Recent Gas, 206.
Battery Boxes, A New Method of Preparing Wooden, 420.
Battery, Secondary, Definition of a, *583*.
Baudot's Telegraph, 619.
Bavaria, The Van Rysselberghe System in, 541.
Baxter Motor, A New, *584*.
Bedford, 4, 345, 618
Bedford and the Electric Light, *52*.
Bedford, Borough of, 71.
Belfast, 445.
Belgian Exhibition in London, 641.
Belgrano (Buenos Ayres), The, Gas Company Bill, 266, 419.
BELL, Dr. LOUIS.
On the Present State of Traction by Storage Batteries, 609.
Problems in Electric Traction, 223, 250.
Bellegarde Central Station, The, 4.
Belt Press, A Large, 542.
Ben Nevis, St. Elmo's Fire on, 643.
BENNETT, A. R.
An Improved Lightning Protector, 375, 459.
Berlin, The Telephone in, 343.
Berwick, Opening of a Telephone Exchange at, 54.
BIDWELL, SHELFORD, F.R.S.
The Electromotive Forces produced by the Contact of Similar Metals at Different Temperatures, 546.
Bifilar Suspensions, The Influence of Humidity on, 276.
Birds Destroyed by Electricity, 465.
Birkenhead, 259, 641.
Birmingham, 82, 543, 618, 642.
Birmingham Electric Lighting, 55
Birmingham, Electric Tramways in, 395, 647.

Birmingham Exhibition, The, 25, *136*, 188, 215, 300, *337*, 353, 369, 443, 518, 547, 586.
Awards, 623, 660.
Brush Electrical Engineering Company (*Method of Lubrication*), 21.
Buller, Johnson and Co., Exhibit of, 519.
Crompton and Co., Exhibit of, 518.
Crompton Electric Crane, The, 518.
Electric Lighting, The, 353.
Goldston Cut-Out, The, 353.
Lacombe and Co., Exhibit of, 518.
Lacombe-Leclanché Cell, The, 518.
Laurence, Paris, and Scott, Exhibit of, 632.
Magnetic Separator, A, 518.
Mordey Alternator, The Fifty Horse-Power, 353.
National Telephone Company, The, Exhibit of, 519.
Sayers and Sturge's Suspension for Electric Lamps, 597.
Scott, Ernest, and Co., Exhibit of, 547.
Snelgrove Electric Weighing Machine, The, 596.
Statter and Co., Exhibit of, 518.
Telpher Line, The, 518.
"Tyne" Dynamo, The, 547.
Woolrich's Magneto-Plating Machine, 548.
Birthday Honours, 81.
Bishop Stortford, 420.
Black Electric Sparks, Some Photographs of Lightning and of, 227.
Blackburn, 263, 465.
Blackpool, 53, 640.
Blackpool Tramway, 166.
Blackrod, 290.
Bleaching Powder, Electrical Production of, 153.
Blenheim Telephones, The, 642.
BLYTH, Prof. JAMES, M.A.
On a New Form of Current-Weigher, 549.
Blyth Current Weigher, The, 485.
Board of Trade Inquiry on the Electric Lighting of the City of Dublin, 142.
Board of Trade Inquiry, The, on the London Electric Lighting Provisional Orders, 14, (*Report*) 56, 148.
Board of Trade Model Order, The, *107*, *185*.
Board of Trade Report, A Professorial Attack upon the, 118.
Board of Trade Rules, The, for Overhead Wires, 412.
Board of Trade, The, Proceedings of, under the Electric Lighting Acts, *263*.
Boat-Lowering Gear, Mills', Sherlock and Pattison's Engine-room Telegraph and, 187.
Bognor, 3.
Bolivia, The Telephone in, 619.
Bolton, 566.
Bombay, The Lighting of the Victoria Station, 619.
Boston (U.S.A.), Electric Railroad at, *72*, *393*, *486*.
Boulevard Electric Lighting Conduit, The, *28*.
Boulevards, Lighting of the, *112*.
Bourganeuf, 517.
Bournemouth, 81, 239, 642.
BRACKEN, J.
Storage Battery Traction, 406.
Bradford, 213, 370, 419, 444, 487, 643.
Bradford Borough of: Proposed Bye Laws in connection with the Corporation Supply of Electricity, 206.
Bradford Central Station, *515*, *549*.
Brand's, Mr., Resignation, *237*.
Brazil, Electricity in, 641.
Brazil, Official Telegraphic Messages in, 161.
Brazilian Order for Cable, &c., 161, 642
Brechin and Edzell, Proposed Telpher Line between, 213.
Bremen, 593.
Brest-St. Pierre Cable, Repair of the, 465.
Brighton, 318 425.
Brighton, Fatal Accident at, 267.
Bristol, 81, 137, 489.
Bristol University College, 443, 465.
British Association at Newcastle, Sketch of the Electrical Papers in Section A, read before the, 544.
British Association, the, Edinburgh and, 444.
British Association, the, Meeting of, 319, 419, *441*, *463*, *485*, 498, *513*.
British Association Lightning Rod Discussion: Dr. Oliver Lodge, F.R.S., 73.

Digitized by Google

v 3-23 incl. 32

British Museum, The Electric Light at the, 444.
Bromsgrove, 317.
Brooks' Underground System, 490, 535, 587.
Brookwood and Bisley Common, Tramway between, 53.
Brown Arc Lamp, The, *371*.
Brown Automatic Safety Apparatus, The, *371*.
Brown, Mr. Harold P., 74, *564*, *578*.
Brunner, 487
Brush Alternate Current Apparatus, The, *290*, *303*.
Brush Electrical Engineering Company (*Method of Lubrication*), 621.
Brush and Thomson-Houston Companies, The Consolidation of the, 578.
Brussels, 265, 584, 659.
Brussels Electric Tramway, The, *368*, 386, 413.
Brusse's, M. Van Rysselberghe's Proposals for the Lighting of, *584*.
Buller, Jobson and Co., Exhibit of, at Birmingham, 519.
Bunsen Cell, Note on the Employment of Chromic Acid instead of Nitric Acid in the. By J. Wilson Swan, M.A., 652.
Burglary at Messrs. Woodhouse and Rawson, 503.
Burnley, 506.
Burslem, 265, 487.
Burton Electric Heater, The, 516.
Burton-on-Trent, 53, 266, 465.
Butler r. the Kensington and Knightsbridge Electric Light Company (Limited), 375.
Buxton, 239.
Bye-Laws, Proposed, in Connection with the Corporation Supply of Electricity, Borough of Bradford, 206.
Cable, A, between Guatemala and the United States, 470.
Cable Repairs, Ocean, 656.
Cable Ship, New Post Office, 81.
Cable Station, Singular Case of Damage from Lightning at a, 244.
Cables for Alternating Currents, The Choice of, 654.
Cables of the Société Française des Télégraphes Sous-Marins, 26.
Cables, Submarine, America and, 246.
Cadiz, Lighting of, 641.
Calcutta, 396, 517, 541.
Calelectric Generator, Acheson's, *395*, 406.
Cambridge, 292, 643.
Canada, The Edison Patent in, 369.
Canadian Transatlantic Cables, The Proposed, *357*.
Canterbury, 265.
Canton, 593.
Cape of Good Hope Telegraph Statistics, 320.
Cape Town, 264.
Carbonate of Soda, The Use of, in Secondary Batteries, 360.
Carbons, Arc Light, Life of, 420.
Cardiff, 239, 265, 541.
Cardiff Telegraphists, The, *418*.
Carhart-Clark Standard Cell, The, *508*.
Carstairs Electric Railway, The, 7.
Casting, A Monster, 420.
Cellulose, The Preparation of, by Electrolysis, 318.
Celluvert, 240.
Census Machine, An Electric, 345.
Centennial Celebration, Electricity at the, *43*.

Central Lighting Stations—

A Private, 643.
Barmen, 55.
Bath, *120*, 655.
Bradford, *513*, *540*.
Deptford, *539*, 586.
Ealing, 160.
Glasgow, 27.
London Bridge, 25.
Montlucon (Allier), 239.
Narragansett, *455*.
Palais Royal, Paris (Paris Congress), 453.
Paris Municipal, The, *28*, *375*, 396.
Zurich, 421.

Central Station Instruments, The Richard Registering, 652.
"Centralblatt für Electrotechnik," The, 239.
Chandler High-Speed Engine, The, 204.
Charterhouse Science and Art Schools and Literary Institutions, 486.
Chatham, 213, 266.
Chelmsford, 344.
Chelsea, 161.
Chelsea and Crompton Systems of Storage Distribution, The, *565*.
Chelsea Electricity Supply Company's Installation, The, 403, 576.
Cheltenham, 240, 542, 618.
Chemistry of Storage Batteries, Contributions to the. By G. Frankland, D.C.L., F.R.S., 470.
Chenoweth Electrical Conduit, The, 521.
Chester, 395, 488, 515.
Chesterfield, 264.
Chili, Import Duties in, 619.
China, The Telegraph in, 291.
China, The Van Rysselberghe System in, 618.
Chiswick, 291.
Chromic Acid, Note on the Employment of, instead of Nitric Acid in the Bunsen Cell. By J. Wilson Swan, M.A., 652.
Cincinnati, Electric Railroad at, *42*.
Cincinnati, Gas *v.* Electricity at, *458*.
City and Guilds of London Central Institution, 568.
City Notes, 21, 49, 77, 105, 133, 157, 183, 209, 235, 261, 287, 313, 339, 365, 391, 415, 439, 461, 483, 511, 537, 563, 589, 615, 637, 662.
City of London and Southwark Subway, 344.
City of London College, The, 488.
Civil Engineers, Institution of, 81, 109.
Classification of Telegrams, Proposed, in France, 567.
Claude Telegraph Apparatus, The, 53.
Clee Local Board, 291.
Clerkenwell Vestry, 317.
Club Lighting, 541.
Coal Digger, The Sperry Electric, 228.
Coast Communication: Tory Island, 215.
Coastguard Stations and Telegraph Offices, 81.
Coatbridge, Airdree and, 264, 343, 487, 566.
Coefficient of Self-Induction, A Method of Measuring the, by Means of the Telephone, 434.
Coils and Solenoids, Magnetic Field of, 13, 93.
Collieries, The Electric Light in, 239.
Column Printing Telegraph, The, *442*, 587.
Commercial and French Cable Companies, The, *330*.
Communication, Electrical, with Light Vessels, 267.
Commutators, A Slide-rest for, 401.

COMPANIES' MEETINGS, REPORTS, DIVIDENDS, &c.

(Abbreviations:—Div., Dividend; Mtg., Meetings of Shareholders; Rev., Revenue; Rpt., Reports of Directors).

Aluminium Company—Mtg., 334.
Anglo-American Brush Electric Light Corporation—133; Rpt., 285; Mtg., 308, 330, 364, 390, 589.
Anglo-American Telegraph Company—Div., 287, 615; Rpt., 312; Mtg., 333.
Australasian Electric Light, Power, and Storage Company—286; Mtg., 310.
Bell's Asbestos Company—Div., 313.
Birmingham Compressed Air and Power Company—Mtg., 439.
Brazilian Submarine Telegraph Company—Div., 133, 589; Rev. 21, 49, 77, 105, 133, 157, 209, 235, 261, 287, 313, 339, 365, 391, 415, 439, 461, 511, 537, 563, 589, 615, 637, 663; Mtg., 18, 638.
Chili Telephone Company, 415, 483.
City of London and Southwark Subway Company—615; Mtg., 390.
Commercial Cable Company—461; Div., 511.
Compagnie Continentale Edison—133; Rept., 105; Mtg., 133.
Consolidated Telephone Construction and Maintenance Company—Rpt., 77; Mtg, 103: Div., 637.
Crompton and Co.—Mtg., 258.
Cuba Submarine Telegraph Company—Rev., 21, 133, 261 365, 461, 563; Mtg., 102, 362; Div., 313; Rpt., 338.
Devon and Cornwall Electric Light and Power Company—415.
Direct Spanish Telegraph Company—287; Rev., 21, 133, 235, 365, 461, 589; Div., 235; Mtg., 537, 561.
Direct United States Cable Company—Rpt., 284; Div., 287, 615; Mtg., 332.
Eastern Telegraph Company—Rev., 21, 133, 339, 461, 563, 589; Mtg., 260, 281, 306; Div., 563, 589.
Eastern and South African Telegraph Company—Div., 183.
Eastern Extension, Australasia and China Telegraph Company—Div., 287, 537, 637; Rev., 21, 133, 235, 339, 461, 563; Mtg., 635; Rpt., 614.
Edison-Swan United Electric Light Company—82; Div., 261; Rpt, 284; Mtg., 336.
Electric Apparatus Company—365.
Electric Construction Corporation—124; Mtg., 561.
Electrical Accessories Company, 663.
Electrical Automatic Delivery Box Company—365, 663.
Electricity Supply Company of Spain—615.
Elmore's Foreign and Colonial Patent Copper Depositing Company—563; Mtg., 587.
Elmore's Patent Copper Depositing Company—49; Mtg., 75.
Endolithic Ivory Company—483.
Exeter Electric Light Company—287; Mtg., 311.
Falcon Engine and Car Works—Mtg., 311, 415.
Fowler-Waring Cables Company—415.
German Union Telegraph and Trust Company—Mtg., 182.
Globe Electrical Engineering Company (Change of Name)—615.
Globe Telegraph and Trust Company—Div., 287, 589; Rpt., 312; Mtg., 334.
Great Northern Telegraph Company—Rev., 21, 133, 261, 365, 461, 589.
Halifax and Bermudas Cable Company—186; Mtg., 510.
Hamburg-Heligoland Cable—105.
Hastings Electric Light Company—Mtg., 104.
Hong Kong Electric Company—Mtg., 312.
India Rubber, Gutta Percha, and Telegraph Works Company—Mtg., 260.
Indian Light Railways—483.
Indo-European Telegraph Company—Div., 663.
Keswick Electric Light Company—Mtg., 364.
Lancashire and Cheshire Telephonic Exchange Company—Rept., 133; Mtg., 156.
London Electric Supply Corporation—Mtg., 282.
Manchester Edison-Swan Company—Mtg., 203; Rpt., 208.
Manganese Bronze and Brass Company—Div., 415.
Maxim-Weston Electric Company—Mtg., 47.
M'Culloch, Sons, and Kennedy—183.
Metal Recovery Company—183.
Mexican Telegraph (Cable) Company—Rev., 21.
Mexican Telephone Company—Rpt., 77.
Mining and General Electric Lamp Company—183.
Monte Video Telephone Company, The—Rpt., 615; Mtg., 636.
National, The, Telephone Company—261, 439, 461, 663; Mtg., 127, 233.
New Telephone Company, *In re* the—124.
Newcastle and District Electric Lighting Company—Mtg., 47, 48.
Newcastle Electric Supply Company—4.
Northampton Electric Light and Power Company—Mtg., 615.
Railway Electrical Contractors—365.
Reuter's Telegram Company—Div., 537.
Schmidt-Douglas Electric Company—365, 439, 483, 615.
Scottish Electric Supply Company—207.
Series Electrical Traction Syndicate—235.
Sheffield Telephone Exchange and Electric Light Company—Mtg., 77.
South of England, The, Telephone Company—Rpt., 183; Mtg., 207.
Spanish National Submarine Telegraph Company—105, 133.
Submarine Cables Trust—Div., 49, 563; Rpt., 76; Mtg., 101.
Submarine Telegraph Company—Mtg., 101, 181.
Taunton Electric Lighting Company—Mtg., 637, 662.
Telegraph Construction and Maintenance Company—Div., 235; Mtg., 282.
Telephone Company of Austria—Rpt., 313; Div., 563.
Union Electric Company of Australia—77.
United River Plate Telephone Company—Rpt., 338; Div., 339; Mtg., 363.
United Telephone Company—Div., 77; Rpt., 105; Mtg., 130, 232.
West African Telegraph Company—Div., 183; Mtg., 243; Rpt., 283.

NEW COMPANIES REGISTERED.
The following Companies have been registered under the Limited Liability Acts:—
  Alcoy and Gandia, The, Railway and Harbour Company, 439.
  Bath Electric Light Company, 49.
  Birmingham House-to-House Electricity Company, 233.
  Birmingham Safe Deposit Company, 603.
  Brush Electrical Engineering Company, 391.
  Cambridge University and Town Electric Lighting Company, 233.
  Chili Telephone Company, 260.
  Column Printing Telegraph Syndicate, 391.
  Crompton Electric Supply Company of Australia, 209.
  Crompton-Howell Electrical Storage Company, 49.
  Croydon Electric Supply Company, 261.
  Devon and Cornwall Electricity Supply Company, 261.
  Dutton and Co., 261.
  Economic Gold Extraction Company, 589.
  Ecuador Telephone Company, 261, 237.
  Electric Arms and Ammunition Syndicate, 615.
  Electric Trust, 233.
  Electric Wiring and Fittings Company, 511.
  Electrical Accessories Company, 663.
  Electrical Tramcar Syndicate, 21.
  Electricity Supply Company of Spain, 183, 589.
  Electricity Supply Corporation, 183.
  Elmore's Foreign and Colonial Patent Copper Depositing Syndicate, 157.
  Fowler-Waring Cables Company, 391.
  General Electric Company, 339.
  Halifax and Bermudas Cable Company, 105.
  Hamilton, Griffin and Co., 563.
  Henley's Telegraph and Electric Construction Company, 261.
  Hulett (D.), and Co., 865.
  Irish House-to-House Electricity Company, 233.
  Jensen Electric Manufacturing Company, 21.
  Johannesburg Electricity Supply Company, 415.
  Keswick Electric Light Company, 21.
  Kingston-upon-Hull Electric Lighting and Supply Company, 261.
  Lancashire and Cheshire House-to-House Electricity Company, 233.
  Leicester Electric Light and Power Company, 261.
  Liverpool House-to-House Electricity Supply Company, 233.
  Llanelly Electric Light and Power Company, 663
  Lothammer Gas Manufacturing Company, 21.
  Macintosh (Chas.) and Co., 537.
  Manchester House-to-House Electricity Company, 233.
  Maquay Syndicate, 589.
  Mexican Southern Railway, 49.
  Midland Engineering Company, 615.
  Midland House-to-House Electricity Company, 233.
  Municipal Electric Light and Power Corporation, 157.
  National, The, Electric Supply Company, 663
  New Spanish Electrical Company, 589.
  Northern Electric Wire and Cable Manufacturing Company, 233.
  Northern House-to-House Electricity Company, 233.
  Peru Telephone Company, 261.
  Pontypridd Electric Lighting Company, 21.

New Companies Registered (*continued*)—
  Portsmouth and South Hants Electricity Supply Company, 105.
  Ruston, Proctor, and Co., 318.
  Schoth's Electro-Medical Apparatus Company, 261.
  Scottish House-to-House Electricity Company, 233.
  Series and General Electric Traction Company, 233.
  South of England House-to-House Electricity Company, 233.
  Stanhope Water Engineering Company, 439.
  Western House-to-House Electricity Company, 233.
  Westinghouse Electric Company, 287.
  Wild (John) and Co., 563.
  Williamson Electrical and Engineering Company, 511.
  Woking Electric Supply Company, 133.
  Wolverhampton Electric Light and Power Company, 209.
  Woodhouse and Rawson United, 313.
  Yorkshire House-to-House Electricity Company, 233.

Newport, 567.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATE JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 573.—Vol. XXIII. FRIDAY, MAY 10, 1889. Price Fourpence.

NOTES.

The following is a translation of a circular signed by M. Mascart, as President of the International Congress of Electricians to be held in Paris from August 24th to 31st, and which we are requested to publish :—

"The International Congress of Electricians, which was held in Paris in 1881, marked an important date in the history of Electricity. The fixture of the practical units has had an influence upon the development of the science and of the industry whose importance it would be difficult to exaggerate. The ease and rapidity with which the decisions of the Congress were accepted, as well in the workshop as in the laboratory, demonstrates the utility of these assemblies, where all the talent and all the skill of the scientific world is brought to bear upon a common end.

"The International Exhibition of 1889 affords an opportunity for continuing and completing the work of 1881. Not that the new Congress will have to deal with problems of so general or so high an order as its predecessor, but many questions have yet to be decided upon which a common understanding, or at least an interchange of views, is desirable. In the programme which has been prepared the Committee of Organisation has not pretended to indicate all the subjects of discussion ; still less does it seek to impose any limit upon the activity of the Congress. It has merely desired to call attention to those subjects which appear to possess the most general and immediate interest.

"We believe that we are in accord with the unanimous sentiment of electricians in putting in the first line the following questions :— The practical measurement of electrical energy in all its forms : The measurement of current in absolute value by means of a standard easy to reproduce : Electric meters for direct and alternating currents : A practical standard of light : The definition of the constants of a machine upon a commercial basis.

"We hope that the *savants* and the manufacturers who have contributed to the progress and to the applications of electricity, and all persons who interest themselves in this novel department of human activity, will respond to this appeal, and will aid in giving to this reunion the importance and the authority of its predecessor.

"(Signed) E. Mascart."

The circular proceeds to give the full programme as drawn up by the Organising Committee, which, however, was published in this journal on December 14, 1888. Any one may become a member of the Congress on forwarding the sum of twenty francs to the President, at No. 44, Rue de Rennes, Paris.

At the *conversazione* of the Royal Society, held on Wednesday evening last, there were as usual many objects of interest to electricians, although the number of strictly electrical exhibits was not perhaps so great as on some former occasions. In one of the bays of the Principal Library Mr. Shelford Bidwell exhibited his beautiful experiment showing an effect of light on the magnetisation of iron (for which see *The Electrician* of March 22nd). Here also Dr. Gore displayed his Voltaic balance, (*The Electrician*, July 20th, 1888), an instrument which has not hitherto attracted much notice beyond the Royal Society itself, but which, we venture to predict, will before long be recognised as embodying a discovery of well-nigh the highest value and interest. Dr. Gore will not let us tell all we know about this matter just at present, but we hope that shortly our readers will have an opportunity of learning from Dr. Gore himself what this instrument is able to accomplish—and possibly they will be not a little surprised. Mr. J. W. Swan showed a little Gramme ring armature carrying a current of about half an ampere, and so delicately balanced that it rotated under the influence of the earth's magnetism alone. Mr. Killingworth Hedges exhibited an ingenious automatic safety device applied to a Kapp transformer. This consists of a small "vacuum tube" in an earth circuit, and so arranged that if the leakage current exceeds a certain amount it actuates a relay which short-circuits the primary. Mr. Vernon Boys exhibited a pair of gold leaves carrying an electric charge, and suspended from a quartz hook under a glass receiver, in an atmosphere kept moist with a dish of water. Here, where a glass support would allow the charge to be dissipated in a few seconds, the quartz maintains the insulation for four or five hours. It is still more strange to learn that if the quartz be actually dipped in water and put back in its place it insulates apparently as well as before. It is clear that henceforth nothing but quartz should be used wherever surface leakage has to be reduced to a minimum. Profs. Rücker and Thorpe exhibited a set of maps illustrating the direction and magnitude of the regional magnetic disturbing forces in the British Isles.

The above list completes the enumeration of the specifically electrical exhibits, but there were several others in which electricity played a part. Of these the most important was the Chronograph, exhibited by Captain Holden, R.A., for measuring the velocity of projectiles and small periods of time. Captain Holden has brought this apparatus to a state of great perfection. Prof. Norman Lockyer performed some most interesting experiments illustrating the probable origin of the aurora spectrum. Prof. W. N. Hartley showed some singular films of metals and metallic oxides deposited by the electric spark. In the Lecture Room Mr. E. S. Bruce exhibited a very beautiful effect obtained by an instrument which he calls the "Electric Graphoscope." It consists of a thin lath of wood

Digitized by Google

which is rapidly revolved by an electric motor. On this a lantern slide is projected showing, say, a statue. The lath itself is then nearly if not quite invisible, and the image is apparently cast upon the air, giving an effect of bold relief. This is a very striking experiment—more so than it may appear from the description. Mr. MUYBRIDGE'S "Automatic Electro-Photographs," illustrating animal locomotion, excited the greatest possible interest, and this, together with the Tainter Graphophone (exhibited by permission of Mr. H. EDMUNDS), were perhaps the most popular features of the evening.

WE announced some time ago that in accordance with a suggestion made by the Electrical Trades Section of the L.C.C., the Board of Trade had consented to change the Unit of electrical supply from one thousand to ten thousand watt hours. This statement we made upon the authority of the Chairman of the Section; and, moreover, in all the Provisional Orders of the London Electric and the Metropolitan Companies the Unit is taken at the higher value. It will, however, be seen from our report that on the last day of the Board of Trade Inquiry, Major MARINDIN, much to the surprise of the counsel, stated that he understood the Board had decided not to sanction any change. In reply to a letter of inquiry we have received the following communication from the Secretary :—

"Board of Trade, Whitehall-gardens, S.W.

"SIR: In recent Licenses the Board of Trade have not made any alteration in the unit of supply.

"This decision was arrived at in consequence of careful consideration of advice given by a Committee of the Council of Electrical Engineers subsequently to the earlier representations to which you refer.—Yours faithfully,

"(Signed) COURTENAY BOYLE.

"May 9, 1889."

It is to be regretted that the Council of the Electrical Engineers should give contrary advice to that of the Electrical Trades on a point which involves no considerations of a scientific or even a technical character, but is purely a matter of commercial convenience.

THE United States' Patent Office has once more sprung a mine upon the unsuspecting and long-suffering electricians of that country. Seven years ago it appears that Mr. ED. WESTON filed an application for the grant of letters patent on the use of insulated iron plates in building up the core of an armature—a device which, it need hardly be said, is now of universal application. An "interference" was, however, entered by EDISON, who claimed the priority, and this has delayed the issue of the patent until the present time. The principal claim now admitted runs as follows :—

"1. In a dynamo-electric machine, the combination, with the shaft, of a cylinder or hub of insulating material secured thereon, iron plates or rings strung over said hub, and plates or sheets of insulating material interposed between said rings, these parts being constructed and combined in substantially the manner set forth for the reception of the coils."

The patent has been issued to the United States Electric Lighting Company, as assignees of ED. WESTON, but as we announced not long ago, this concern has passed into the hands of the Westinghouse Company, and already we hear that an infringement suit has been entered by the latter against the Fort Wayne Jenny Company. However superior the United States' Patent Laws may be to our own in some respects, it certainly appears that the operation of an "interference" sometimes causes grave injustice to be done, especially as an outsider has no means of knowing what applications have "interferences" pending, nor does an inventor know when, if ever, a patent may be issued to him.

WE understand that a scheme is on foot for the holding of an International Electrical Exhibition next year in Edinburgh. Judging from the success which has already attended the Birmingham Exhibition—where applications for space have far exceeded expectation—there can be little doubt that an Exhibition next year in Edinburgh, when counter-attractions will probably be less formidable, should prove an even greater success.

A STRONG feeling of indignation has been aroused amongst the holders of the instruments of the New Telephone Company by the manner in which the Directors have been induced to abandon them to the tender mercies of the Company whose patents are alleged to have been infringed. When it is understood that upwards of 8,000 instruments (every one bearing the inscription "fully guaranteed") have been disposed of, it will be admitted that the conduct of the Directors demands a further explanation than it has yet received. Whether or not it was the duty of the New Company to have resisted the claims of the United in a Court of Law is a point upon which we would express no opinion either one way or the other. It is useless to argue the question whether or not the "valve" transmitter is free from the Edison patent upon its own merits. If, when matters came to a crisis, the Directors arrived at the conclusion that their position was untenable, no doubt they should be praised rather than blamed for having avoided a further loss of the shareholders' money. But then of course they should have satisfied themselves on this point years ago, when the Company was first started; and meanwhile, what did they mean by "fully guaranteed?"

THERE is another point on which further information is very desirable. How comes it to pass that the United Telephone Company are demanding the surrender of the receivers as well as the transmitters? It is well known that the receivers of the New Telephone Company are made with the parchment diaphragm, which BELL found it necessary to disclaim. We need not go into the rights or wrongs of the manufacture, nor need we stay to inquire whether BELL or REISS was the true inventor of this type of receiver, but we do want to know upon what legal ground the United Telephone Company are actively confiscating the instruments. Information in our possession would lead us to believe that this step has been taken in consequence of an agreement between the respective companies, in virtue of which the Directors of the New Company are not to be held personally responsible for any infringement of which they may have been guilty upon condition that the receivers as well as transmitters were surrendered. If this be correct, we ask again, what becomes of the "full guarantee?"

Digitized by Google

In view of recent action on the part of the English Telephone Companies, it is interesting to note that the American Bell Telephone Company is contemplating extensions on a very large scale to meet the demand for long-distance telephony. A petition has just been presented to the Committee of Mercantile Affairs by the above-named Company, praying for permission to increase its capital from ten million dollars to twenty million, the extra capital being needed chiefly for the erection of long lines. The wires being of copper, and doubled for each circuit, the neccessary expenditure will be far in excess of that required for similar lines of telegraph. Some of the lines are to consist of as many as 100 wires, and will cost $5,000 a mile. It is proposed to spend $7,000,000 or $8,000,000 in this way within the next three or four years if the Legislative Committee accede to the Company's petition.

As to the future of long-distance telephony, however, it is probably as unsafe to predict anything, one way or the other, as it was of long-listance telegraphy forty-two years ago. Mr. R. S. Cully, in the current number of *Blackfriars* (the Post Office magazine), recalls some of his experiences relating to that period, and among them his being discharged, or rather served with notice of dismissal, with a number of other officers, by the Electric Company in anticipation of its being *wound up!* So little did the public avail themselves of the telegraphic facilities then offered to them, that notwithstanding the most niggardly expenditure on its staff of employés, the Company decided to abandon the enterprise altogether as being financially a failure. Happily, before the notices expired better prospects set in; and a few years later the Electric Company was in a flourishing condition, which went on improving rapidly until 1870, when the country was glad to buy it out at a very handsome premium. It is not to be supposed that the collapse of the pioneer company would have extinguished electric telegraphy; but it must have been greatly delayed had not the Company plucked up courage to carry on the extensions so as to make them continuous and comprehensive. It attracted little notice while the lines were short disjointed lengths connecting one important town with another; but directly they were all joined together, and the system assumed a cohesive shape, business began to flow in and success was assured.

We understand that the negotiations between the Metropolitan Railway Company and the Electric Traction Company with reference to the working of the Metropolitan service by accumulators have now been definitely abandoned. We are neither sorry nor surprised at this result—in fact, we think that each company is to be congratulated on not having proceeded further with a scheme which from the first we have regarded as impracticable. More than a year ago, in our issue of April 27, 1888, we stated our reasons for this belief, but we also expressed a confident opinion that a well-considered scheme of direct current working would prove both practicable and economical. Subsequently, Mr. Sidney Evershed wrote a series of articles (*Electrician*, August 10, 1888, *et seq.*) in which the conditions of the problem were very fully considered. We should be delighted to hear that the Electric Traction Company had again taken the matter in hand on some such lines as those indicated.

Our American Notes have been delayed in transit and arrived too late for insertion this week.

Bognor.—The Local Board of Bognor are prepared to receive tenders for the lighting of the streets of that town by electricity. Further particulars will be found in our advertisement columns.

Personal.—We learn that Mr. A. E. Mavor, having completed his electric lighting duties at the Forth Bridge, has been appointed manager of the electrical department of Messrs. William Denny and Bros., Dumbarton.

St. John's.—The Town Council of St. John's (Canada) has decided to have the streets of that town lighted by electricity, and has signed a five years' contract with Messrs. C. F. Beauchennie and Co., of St. Jerome.

Elektrotechnische Zeitschrift.—We are informed that Herr Wabner has resigned the editorship of the *Elektrotechnische Zeitschrift* "on account of official promotion," and that Herr Petsch has now become editor of that journal.

Elieson Sale.—It will be seen by our advertisement columns that Messrs. Wheatley Kirk, Price and Goulty are instructed to sell piecemeal the entire plant and effects of the Elieson Electric Company. The sale will take place about the end of the present month.

Hull.—A meeting was recently held in Hull to consider the question of forming an electric lighting company, and it was decided after some discussion that the promoters should canvass the business part of the town, with a view to subsequently approaching the Corporation on the matter.

The Telephone in Cuba.—The *Gazeta de Madrid* invites tenders before the 28th June next for the installation and working of a telephone service in Havana. Tenders had previously been received and a contract awarded, but it fell through owing to the contractor not having made the required deposit within the period agreed upon.

Holborn Board of Works.—At a meeting of this Board on Monday last a letter was received from Messrs. Rooper and Co., on behalf of the Gwynne Electric Lighting Company, asking the consent of the Board to apply to the Board of Trade for a License to supply electricity in the district. The matter was referred to the Committee of Works.

Royal Society.—Mr. A. W. Ward read a Paper yesterday before the Royal Society "On the Magnetic Rotation of the Plane of Polarisation of Light in Doubly-Refracting Bodies," Dr. Hopkinson reading a Paper "On Magnetic and other Properties of Iron at a High Temperature," and Dr. Gore one "On Determining the Strength of Liquids by the Voltaic Balance."

Montreal.—The Royal Electric Company has secured the contract for the public lighting of Montreal. By the 1st July next the contractors are to have 663 2,000 candle-power arc lamps fitted in addition to the 137 already in operation. The lamps are to be kept lighted from dark till daylight at a cost of 40 cents per lamp per night, or about £30 per lamp per annum.

Spanish Telegraphs and the Press.—At the last Cabinet Council in Madrid the Minister of the Interior presented a project for the reduction of the tariff to the Press for messages sent during certain hours when the public service is less pressing. The Bill also provides for the hiring of telegraph wires by the newspapers, the income therefrom to be applied to the improvement of the telegraph service.

The Lighting of the Left Bank of the Seine.—The Conseil Municipal of Paris has granted an electric lighting concession for a district on the left bank of the Seine to MM. Nouvelle et Geisenberger. This district stretches from the river to the fortifications, and is bounded on one side by the Rue Saint Jacque, and the Rue de la Tombe-Issoire, and on the other by

Digitized by Google

the Rue des Saints-Pères, the Rue du Cherche-Midi, and the Rue des Fourneaux.

Institute of Electrical Engineers—Students' Meeting.—A meeting was held on Friday, May 3, Mr. Alexander Siemens in the chair. Mr. Müller opened a discussion on Prof. Forbes' Paper on "Some European Central Lighting Stations and their Lessons." Messrs. W. H. Shepherd, T. L. Horn, C. H. Yeaman, J. N. Cooper, and the chairman continued the discussion. A hearty vote of thanks to Mr. Siemens for presiding terminated the proceedings.

Recent Thunderstorms.—Scotland and the North of England have been visited within the last few days by severe thunderstorms, during which several houses and persons have been struck by lightning. On Monday evening last an extraordinary thunderstorm occurred at Boulogne-sur-Mer; two horses were killed by lightning, and a man and a woman were also struck. The havoc made by the storm gives the town the appearance of having been visited by an earthquake.

Bedford.—At a meeting of the Bedford Urban Sanitary Authority last week the Gas and Electric Light Committee recommended the adoption of the electric light by the Corporation. The Committee gave elaborate statistics showing an estimated immediate clear gain to the borough of about £345 per annum. It was unanimously decided to obtain powers under the Electric Lighting Acts, and to employ an electrician to advise as to the establishment of the proposed installation.

Barnet.—The Barnet Local Board, at a special meeting held on the 25th ult., passed the following resolution unanimously:—"That having regard to the unsatisfactory manner in which Messrs. H. F. Joel and Company have lighted, and are lighting, the district of the Barnet Local Board, this authority do not consider it necessary or advisable to assent to or assist the undertakers in obtaining any powers from the Board of Trade under which they would acquire full control of the lighting of the district of this authority."

"Engineering" (Paris Exhibition Number).—Our contemporary, *Engineering*, issued last week a special double number in connection with the Paris Exhibition, which affords a most remarkable illustration of the enterprise of technical journalism in this country. The issue consisted of no less than 240 pages, of which 136 contained advertisements. The Exhibition Supplement consisted of 88 pages, and contains 254 engravings. It is scarcely necessary to add that the descriptive matter is fully up to our contemporary's usual high standard of excellence.

Reading.—At the meeting of the Reading Town Council last Thursday, the Highway Committee reported that the Chairman and one member of the Committee had been appointed a Sub-Committee to consider the whole subject of the lighting of the town, in view of the approaching termination of the existing contract with the Reading Gas Company, with a request that they would confer on the subject with the Gas Company, and with Messrs. Laing, Wharton and Down, who have established works in Reading, and whose lamps have recently been tested for a month in the centre of the town.

Ipswich.—At the monthly meeting of the Ipswich Scientific Society on Wednesday evening last week, Mr. W. B. Sisling, local representative of Messrs. Laurence, Paris and Scott, delivered a lecture on the "Transmission of Energy by Electricity." Mr. Sisling practically exemplified the electric transmission of power by sending the current on a small scale necessary to light two 16-candle lamps from two small dynamos in series through many yards of the finest iron wire. Mr. Sisling's lecture was listened to with the greatest interest. Several questions were asked of the lecturer, and a hearty vote of thanks to him concluded the meeting.

The Bellegarde Central Station.—The central lighting station at Bellegarde (Ain), which has been in continuous operation since February, 1884, and which at the present moment has an output of 3,500 horse-power, has lately inaugurated a system of electrical distribution for power purposes. The charge is 200fr. per horse-power per annum up to 50 horse-power, and 150fr. per horse-power per annum over that amount. The current is on day and night. For motors of less than 40 horse-power and within a kilometre of the station the pressure is 100 volts; for larger motors and longer distances 300 volts are employed.

Export Catalogue of Machinery and Hardwares.—The fourth annual edition of this useful publication, which is brought out by the Machinery and Hardware Company, now extends to close upon 150 pages, and contains the quotations of a large number of well-known firms. By means of this catalogue manufacturers are enabled at a greatly reduced individual cost to bring their specialities prominently before buyers all over the world. The catalogue is published annually, and copies are circulated all over India, the Colonies, and the Continent generally. The list of electrical firms making use of this medium contains first-rate names, but the number is very small indeed.

Newcastle Electric Supply Company.—On May 6th the statutory first general meeting of this company was held at its offices, 1, St. Nicholas's-buildings, Newcastle, Alderman T. G. Gibson in the chair. The Chairman explained that the consent of the Newcastle-upon-Tyne Corporation had been obtained to the Company's License, and that the Company's License had been favourably considered by the Board of Trade, who had intimated that it would be granted at the end of the statutory period. The Chairman further stated that a site had been acquired for the company's works, tenders for buildings accepted, and plant ordered and in course of construction. The directors were re-appointed with important additions, and a vote of thanks to the Chairman closed the proceedings.

Exports of Electrical Apparatus.—The Board of Trade returns for April, issued this week, are again of an exceptionally favourable nature. The April shipments of telegraphic wire, &c., were small, but that is not surprising having regard to the abnormally large exports of March last. The following is a comparative statement of the exports of wire, &c., for the month and for the four months:—

	1887.	1888.	1889.
January.....	£14,442	£41,231	£112,230
February ...	44,137	14,051	32,086
March	73,300	32,795	285,993
First quarter	£131,879	£88,077	£430,309
April	27,616	27,012	13,032
Four months	£159,495	£115,089	£443,341

Liverpool.—At a meeting of the Liverpool Town Council on Wednesday last week, Alderman John Hughes moved that the consent of the Council be given to the request of the Liverpool Electric Supply Company for the consent of the Corporation to their application to the Board of Trade for a Provisional Order. The term for the powers of the company is twenty-one years, and at the end of that time it will be competent for the Corporation to acquire the rights of the company at arbitration. A maximum rate of interest to the shareholders of the company has been fixed; after 7 per cent. has been paid the interest beyond that amount is to be divided, one-half going to the shareholders and the other half being devoted to the easements of the rates. Under the company's agreement with the Corporation the latter also has power to audit the accounts of the company and to examine their books. The resolution was adopted.

Paddington and the Electric Light.—At the last meeting of the Paddington Electric Lighting Committee the following resolutions were carried:—

"1. That while the Report of Prof. Forbes, F.R.S., M.Inst.C.E., shows that the Vestry might secure many advantages to the Borough by itself undertaking the introduction of the electric light, before coming to any decision on the question steps be taken to obtain proposals for doing it by private enterprise, so that the several schemes may be compared and considered in time for the Vestry to agree to the necessary notices and applications being made under the Electric Lighting Acts for the Session of 1890.

"2. That in order to carry out this policy a Sub-Committee of seven members be appointed to obtain by advertisement or otherwise proposals from companies and others for the supply of electricty for lighting purposes.

"3. That it be an instruction to the Sub-Committee to arrange that all proposals shall be sent in on a uniform basis, to be subsequently agreed upon at an adjourned meeting of this Committee, subject first to approval by the Vestry."

THE ELECTRIC LIGHTING OF THE PARIS EXHIBITION.

Although the earning capacity of an Exhibition depends to so large an extent upon the total number of hours during which the public has access to it, and although the adoption of the electric light is such an important factor in increasing the number of "working" hours, the French Government have preferred to hand over the electric lighting of the Exhibition to a syndicate rather than undertake the matter themselves, or pay for the light at a fixed rate as in the case of gas. The following details of the lighting will be of interest at the present moment.

The idea of undertaking the lighting on the present lines occurred at an early date to M. G. Berger, who suggested it to the Chambre Syndicale des Électriciens. The Chambre Syndicale forthwith delegated MM. Lemonnier and Hippolyte Fontaine to study the subject and enter into communication with the State. The upshot of these inquiries and negotiations was that the Minister of Commerce and Industry gave permission to the Syndicate International, upon certain well-defined conditions, to light the Palais des Machines, the gardens on the Champs de Mars, and various other sites in the vicinity. The agreement and statutes of the syndicate, accompanied by a *cahier des charges* drawn up for the Commission Technique d'Électricité, of which M. Mascart is president, were signed on the 15th February, 1888. The Syndicat International des Électriciens is a company with a capital of 300,000fr., founded by the firms of Gramme, Edison, Sautter-Lemmonier and l'Éclairage Électrique, and its object is to undertake the private and public electric lighting of the Exhibition. The Conseil d'Administration appointed by statute consists of MM. Fontaine, Lemonnier, Raw, and Fabry. The profits of the concern are to come from the gate-money received of an evening, the price of admission being 2fr. on week days and 1fr. on Sundays. The syndicate agrees to give the State half the gross receipts up to 3,600,000fr.; when the receipts exceed this sum the portions to be given to the State will be seven, eight, and nine-tenths of the gross receipts until they reach the sum of 4,600,000fr. Some 26 firms replied to the circular sent out by the syndicate; of these 16 were French, 5 Belgian, 2 English, 2 Swiss, and 1 Alsatian. M. de Bovet was now made chairman of the company, M. Picou chief engineer, and MM. Napoli, Dumont, Révérénd and Lafon inspectors of works. The public lighting is carried out as follows:—

Buildings.—The Palais des Machines is a magnificent hall 383 metres long, 114 metres wide, and 45 metres high, with two galleries 18 metres in width running all round it, the total floor space amounting to 77,000 square metres. The lighting is provided by two independent sets of apparatus. The first set comprises no less than 48 arcs taking 60 amperes each—they are without globes, and are placed at an elevation of 40 metres. These huge lamps are supplied by the Gramme Company. The second set comprises 86 25-ampere arcs, placed in five rows at an elevation of 15 metres. These lamps are supplied by the following firms:—Crompton, 24; Ducommun, 20; Sautter-Lemonnier, 12; Jaspar, 10; Société Belge, 6; Borssat, 6; Société Française, 4; Henrion, 4. The upper gallery will be lighted by 276 8-ampere arcs placed at a height of five metres. Of these Crompton furnishes 79; Ducommun, 76; Sautter-Lemonnier, 30; Oerlikon, 25; Société Française, 8; Société Belge, 8; Henrion, 8; Jaspar, 7; Popp, 5. The staircase in the transverse axis, near the École-Militaire, will be lighted by 200 eight candle-power Woodhouse and Rawson lamps; the offices under the staircase by Garnot with 10 250 candle-power lamps; the staircase opening out on to the Avenue de Suffren by Jarriant with 360 eight candle-power lamps; and the staircase near the Avenue de la Bourdonnais by Crompton with 160 eight candle-power lamps.

The railway annexe, with a superficies of 5,718 square metres, is illuminated by five 25-ampere and 30 8-ampere Borssat arc lamps. The Société des Forges et Chantiers de la Méditerranée lights the hall in front of the grand staircase with 10 8-ampere arcs and 320 10 candle-power incandescents. The gallery uniting the hall and the central dome is supplied with 48 8-ampere Cance lamps, the dome itself being lighted by 48 500 candle-power lamps supplied by the Gramme Company. The buildings at the back of the Bureau des Brevets is lighted by 16 "Soleil" lamps. The front of the building is illuminated by 16 8-ampere and three 16-ampere arcs, furnished by the Société pour la Transmission de la Force Motrice par l'Électricité. The Gramme Company will light the staircases by eight 500 candle-power incandescents, and the upper gallery by 10 500 candle-power incandescents. The Edison Company has installed three groups of 6 8-ampere arcs in the Galérie Rapp, as well as 26 8-ampere arcs generally distributed. The same company provides 400 8 candle-power lamps in the "Pavillon de l'Administration et de la Direction Générale."

Open Spaces.—These are lighted by 18 8-ampere arcs furnished by the firm of Ducommun, of Mulhouse, and by 22 arcs supplied by the Edison Company.

Upper Garden.—The lighting of this garden has been entrusted to the Société pour la Transport de la Force and to the Société pour la Soudure des Métaux. The former employs 72 8-ampere arcs, and the latter 850 4 candle-power and 100 8 candle-power lamps.

Central Garden.—The lighting of this garden is in the hands of the Edison Company and the Société d'Éclairage Électrique. The Edison Company has installed 33 8-ampere arcs, 100 8 candle-power, and 5,000 4 candle-power incandescents.

Lower Garden.—The lighting of this section comprises 60 8-ampere and 8 25-ampere arcs.

The banks of the Seine are lighted by 75 8-ampere arcs.

The illuminated fountains require eighteen 60-ampere and 30 40-ampere arcs. The total candle-power of the arc lamps amounts to 1,500,000 candles, and that of the incandescent lamps to 100,000 candles.

The electric plant supplying all these lights is grouped together in six central stations. The Gramme station has an area of 640 square metres, and the plant comprises nine Davey-Paxman locomotive boilers, three Davey-Paxman compound engines, developing a total of 700 horse-power, two 175 horse-power dynamos, and three 100 horse-power compound-wound dynamos, giving 110 volts at the terminals. The Edison station has an area of 400 square metres, and the plant comprises four 150 horse-power Belleville boilers, four 150 horse-power Weyher and Richemond engines, two 100 horse-power and six 50 horse-power Edison dynamos. The Jablochkoff station, belonging to the Société d'Éclairage Électrique, has an area of 400 square metres, and a total available power of 600 horse-power. The plant comprises four Terme and Deharbe boilers, four 150 horse-power Lecouteux and Garnier engines, and 19 dynamos, viz., eight Gramme alternators, 10 Rechnervski continuous-current machines, and one Ferranti alternator. The station belonging to the Société pour la Transmission de la Force contains two 500 horse-power Corliss engines, fed by multitubular Roser boilers and four 200 horse-power Marcel-Deprez dynamos. The Ducommun station contains 15 dynamos, having a total output of 300 horses, supplied by Lagosse boilers and Ducommun engines. The station belonging to the Syndicat International has an area of 320 square metres, and the total available horse-power amounts to 400, the boilers and engines being of various types. The electrical plant consists of two 100 horse-power Borssat dynamos, one 50 horse-power dynamo, and one 30 horse-power dynamo, together with a Parsons turbo-electric generator. The total power available for electric lighting purposes amounts to something like 4,000 horse-power, in addition to the 10,000 kilogrammes of accumulators.

The well-known firm of engineers, Messrs. Davey, Paxman and Co., of Colchester, whose engines and boilers have acquired a world-wide reputation, have sent to the Paris Exhibition such a fine and various collection of steam motors, generators and mining machinery as will add not only to the credit of the Colchester firm, but will prove to the visitors of the Exhibition that Great Britain still maintains the first position in the manufacture of steam engines and boilers. Messrs. Davey, Paxman and Co. exhibit steam engines and boilers of about 1,500 total horse-power, out of which about 300 horse-power is for supplying the motive power required in the British

Digitized by Google

section. This power is given off by two engines, both of which are condensing, one of the coupled compound girder type and the other of the horizontal girder frame type. The remaining power, which is used for driving electric lighting machinery, consists of three engines, all of the compound receiver type, one 500 horse-power coupled compound girder engine and two of the well-known "Colchester" type. One small horizontal engine is used for driving the mechanical stokers of the group of nine locomotive multitubular boilers which are supplying the necessary steam for the engines.

(FROM OUR SPECIAL CORRESPONDENT).

PARIS, *May* 7, 1889.

The Universal Exhibition was opened on Monday afternoon, at 2 p.m., and remained open until midnight. The crowd was immense, and no less than 250,000 paying entries are said to have been registered. Although it was not ready in the full sense of the word, the Exhibition was in a much more advanced state than is usually the case, and it will be complete in the course of a fortnight. From what was to be seen of the electrical illuminations one may obtain some idea of what it will be when finished, although not half of the lamps were yesterday alight.

The fact that the International Electrical Syndicate, controlling the lighting of the Exhibition, have available some 4,000 horse-power for the purpose will convey some idea of the amount of mechanical and electrical machinery brought into requisition, while the diversified systems of lighting and machinery employed, owing to its international character, lends a special interest to the British electrical engineer. Although only two out of the six large central stations are now running, namely, the Edison and the Gramme, there are three others, the Deprez, the Jablochkoff, and the Syndicate, which are very near completion. The illuminations on the opening night were chiefly supplied by the Gramme-Davy-Paxman Station. At nine o'clock a gun fired from the Eiffel Tower announced the starting of the luminous fountains, the display of which was really marvellous. They played about twenty minutes, and the public frequently cheered and applauded.

The Edison Station ran six 600-light dynamos, with three Weyher and Richemond engines, and produced a most brilliant effect with arc lights in the Galerie Rapp, where the statuary is collected, and round the lawns and walks with incandescent lamps. The Terme and Deharbe boilers which are to supply steam to the Jablochkoff Central Station (Société L'Éclairage Électrique) not being ready in time, the company ran some 90 Jablochkoff candles in the grounds and along the façade of the Palais des Arts Liberaux, by means of three 30 horse-power and one 10 horse-power portable engines running six alternating Gramme dynamos. The improvised mains were overhead, but the permanent "canalisation" is underground, and connects one transformer to each lamp of six candles. This is enclosed in a test box contained in the lamp-post, and all transformers are in series. The potential is neither transformed up nor down, but the transformer simply serves the purpose of preventing a disconnection of the entire circuit when one lamp fails. The whole of the façade of the Palais des Beaux Arts was illuminated by 34 Gramme arc lamps run by a small plant in the machinery hall. This is installed by the Compagnie Electrique, and consists of four high-tension Gramme dynamos, run from a 50 horse-power "Otto" gas engine. The chief interest lay in the method of driving, which was by friction, one countershaft pulley driving two dynamos, the latter being inclined so as to cause the pulleys to grip. Another electric sub-station running from the Machinery Hall was that of Messrs. Sautter and Lemonnier. Some 28 arcs were run to light one of the large restaurants, the plant consisting of an eight-pole continuous current dynamo run direct off a 100 horse-power vertical compound high-speed engine. From this station will also be run 42 arcs, as part of the general illumination of the Machinery Hall. This vast and noble structure presented a far more complete appearance as regards the exhibits than many of the most sanguine, who knew the state it was in a few days ago, could have ventured to anticipate. Edison's prominent *emplacement* draws attention immediately. Here are phonographs and an array of the latest telegraphic devices, in addition to a complete central-station plant on the three-wire system, underground conductors, dynamos, switchboard, and regulating appliances. The dynamo, lamps and fittings which are comprised in the Edison "Municipal" system of street lighting by incandescent lamps will attract attention. The gigantic Edison lamp, which has been built up out of some 25,000 incandescent lamps, is to be lighted by a number of red-coloured lamps inside the others, placed in the form of a filament. The 100,000 candle-power arc light placed on the top of the Eiffel Tower, and the two search-lights of the same candle-power erected on the platform at 280 metres from the ground, produced a splendid effect, and were also very much admired. The height of the top of the lantern above the ground is 984ft., though, so far as the general public is concerned, the Tower terminates at a height of 896ft., where there is a platform some 53ft. square, above which rise four latticed arched girders, uniting at a height of 54ft. above the platform (*see* Figure). By means of a spiral stair-

Summit of the Eiffel Tower.

case yet another gallery is reached, which is 46ft. higher, and above this rises the great lightning rod.

The idea originally propounded was to turn the Tower at night-time into a veritable pillar of fire by the use of innumerable arc and incandescent lamps. On account of the enormous expense, however, the scheme was abandoned, and the electric light is confined to the three large projectors at the summit, each of which is run off its own dynamo, placed at the base of the tower in the south-west leg. The current is taken to the lamps by means of bare stranded copper cables run on insulators. In the lower lantern there are two 100-ampere Mangin projectors made by MM. Sautter, Lemonnier and Co., which are worked by hand, and provided with Morse apparatus for the purpose

Digitized by Google

of flashing military signals. Above these lights is the lantern proper, containing an illuminating apparatus such as is used in the first-class lighthouses along the coast of France, and projecting red, white and blue beams over Paris and the adjacent country. The clockwork hitherto invariably employed in all lighthouses having revolving lights is, however, replaced by an electric motor.

In addition to the lighting, there are several points connected with this great Tower of interest to electricians. During the building of the Tower the telephone proved of great use as a means of communication between the men at work at the top and those engaged below; and the various platforms are now all permanently in telephonic connection with one another. Special provision has been made to protect this huge lightning conductor from lightning. Eight cast-iron pipes, 19in. in diameter, connected to the ironwork of the structure, pass through to the water-bearing strata, 60ft. below the level of the Seine, while at the summit soars a long pointed rod of the ordinary description.

Bent on vindicating the practical utility of the Eiffel Tower, the French have been at great pains to enumerate the various scientific possibilities of the structure. First and foremost, there is the laboratory at the top, for which great things are predicted in the way of meteorological observations and discoveries in atmospheric electricity. Valuable astronomical and optical observations are also expected to be made from the summit, while, according to M. Max de Nansouty, if Paris had possessed *le tour Eiffel* in 1870 the issue of the great siege might have been different. "The optical telegraph, whose functions, combined with secret correspondence, have attained remarkable perfection, would have established permanent communication between Paris, Rouen, and the provinces. Nothing could have stopped or interrupted these signals, which would have contributed to unite all the armies organised in the provinces against the investing forces."

THE CARSTAIRS ELECTRIC RAILWAY.

Messrs. Anderson and Munro, of Glasgow, are now putting the finishing touches to this, the first electric railway in Scotland. It extends from Carstairs House, the residence of Joseph Monteith, Esq., to Carstairs Junction, on the Caledonian Railway system. It has been constructed chiefly as a means of rapid and always ready communication between the station and Mansion House, but it has branches and sidings so that it may serve for local farm and estate traffic. The line runs for a mile and a-quarter through some of the most beautiful scenery on the Carstairs estate. Owing to the absence of all smoke, dirt, or noise, it will not in the least mar the charm of its surroundings. The conductors are rectangular rods of very pure iron, arranged, the positive on the one side, the negative on the other, about a foot outside of the rails. They are attached to specially designed insulators by an elastic steel fastening, which allows of no side shake, but permits the rods to expand freely, and which can be easily replaced should any insulator get broken. The insulators are in turn supported on iron rods, rising some 10in. from the sleepers to which they are attached. The gauge is 30in. A handsome electric carriage is being constructed, and during the trial runs a speed of 35 miles an hour was attained, and could have been easily surpassed. At all speeds the motion was exceedingly smooth and pleasant.

The source of power is a waterfall three miles distant. When the car is at the station end, therefore, the current traverses eight and a-half miles of conductor. As the Mansion House had to be lit throughout by the same current, and as it was necessary to keep the potential difference under 250 volts at the railway to obviate danger from shock, and the size of conductor small on account of its length, it will be seen that an interesting problem was presented for solution. Fortunately there was ample water-power to waste, so a series-wound dynamo of Goolden type, giving 400 volts and about 40 amperes, was placed beside the turbine, and current was carried over the three miles to the Mansion House along four bare copper wires run on fluid insulators. "Earth" is nowhere used, the circuit being metallic and insulated throughout. At the house there is placed a battery of 100 E.P.S. cells, which are charged all in series. This battery, when discharging, has the house wires so joined up that one half supplies one section of the house and the other half another section, although, when lighting lamps only, it can be transformed into one battery of 100 volts, the two halves being then in parallel. The cars can be run from the cells alone, from the dynamo alone, or from both coupled. The varying demands for current produce large variations of field-magnet strength, and consequently of E.M.F. at the terminals of the series dynamo, but, on the other hand, the large line resistance causes fluctuations in the opposite direction in the amount of loss in the line. This loss varies from 10 up to 150 volts. The dynamo characteristic and the line resistance have been so adjusted that within a working range of current strength the potential difference at the house switchboard is approximately 250 volts. An automatic appliance keeps the current flowing always within the desired range, so that even if all load is thrown off there is not more than 250 volts on the railway conductors, nor are the field magnets demagnetised. At present an attendant living near by starts and stops the dynamo on receipt of a signal; but it is the intention to put in a small motor to put off and on the water supply. A pair of smaller brushes will be placed midway on either side between the chief collecting brushes, and the small brushes coupled together are joined to the signalling wire after passing through the armature of the small motor. The field magnets of the motor are a shunt on the main wires. By joining the accumulator end of the signalling wire to the positive or negative main respectively a current flows through the small motor armature in one or the other direction. Thus, by putting a switch at the house to right or to left, the water can be put off or on at the turbine three miles distant. We hope to give drawings of the car when it is completed, showing details of its mechanism. The whole system has been designed by Mr. John M. M. Munro (of Anderson and Munro, the contractors for the work), and carried out under his superintendence. Mr. Monteith, who is himself a skilful engineer, has taken a close personal interest in the construction of this railway, and with Mr. David Hunter, of Lanark, has materially contributed to its success.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"On Lightning, Lightning Conductors, and Lightning Protectors."*

BY DR. OLIVER LODGE, F.R.S.

(Continued from page 734.)

MATERIAL OF THE LIGHTNING CONDUCTOR.

25. A few words may suffice to explain the nature of the impedance which alternating currents meet with in passing through a conductor, and of the reason why iron is as good as, or even better than, copper for the purpose of conveying currents alternating with extreme rapidity.

A rising current has to magnetise the space all around it, and the production of this magnetisation delays and impedes the rise of the current to its maximum value. A falling current permits the magnetisation of the space all round it to decay, and the dying out of this magnetisation delays and impedes the fall of the current to its minimum. The more rapidly the current changes the more powerfully felt is the influence of the accompanying magnetisations and demagnetisations. Now the total magnetisation produced by a current—its total number of lines of force, or its total "magnetic *induction*," as it is often called—is proportional to the current strength; equal to it multiplied by some constant, which we may call L, and write

$$I = L C,$$

where I is the total induction produced by the current C. L is a coefficient characteristic of the circuit, its value being defined by this equation, and is called the coefficient of induction excited by the current's own self, or the coefficient of self-induction.

* Paper read before the Institution of Electrical Engineers on Thursday April 25, 1889.

Digitized by Google

If the current goes through $p/2\pi$ complete alternations in a second, it can be shown that the impedance it meets with, due to the reversals and re-reversals of its own magnetic field, is p L.

This is not the whole obstruction it meets with, but it is the only part which does not dissipate energy and cause its vibrations to decay. It may be called the *inertia* part of the impedance. The remaining part of the total impedance is resistance, R, the dissipation of energy coefficient, defined by

$$\text{heat per second} = \text{R C}^2 ;$$

and the total is the resultant of these two as if they were at right angles to each other. So that, calling P the total impedance,

$$P^2 = (p\,L)^2 + R^2.$$

Now in respect of the R term, iron is much worse than copper, not only seven times worse, hundreds of times worse ; but then for very rapid alternations the R term is altogether insignificant compared with the p L term.

26. In respect of the p L term does the material of the conductor matter ?

Well, in so far as the magnetisation spoken of is that of the space surrounding the conductor, of course the substance of the conductor itself matters nothing. But in so far as the conductor itself gets magnetised, the material of which it is made does matter. Now a linear current magnetises at right angles to itself everything surrounding it—most intensely the things close to it. A hollow cylindrical current magnetises everything outside itself, but nothing inside. If the current were to distribute itself uniformly through the section of the wire, the outside of the wire would get magnetised in concentric cylinders ; but if the current were to confine itself to the outer surface, and flow as a hollow cylinder, it would escape the necessity of magnetising the wire at all. In cases where the p L term is much more important than the R term this is precisely what it does therefore. It always flows so as to meet with the least possible total obstruction ; and it finds less total obstruction by cramping itself into the periphery of the wire than it would find if it utilised the whole section. The cramping into the periphery increases R, but it decreases p L ; and on the whole with rapidly alternating currents this is an advantage, and gives a smaller value to P.

Slowly changing currents think most about R, and use the biggest cross-section they can find. Rapidly changing currents think most about p L, and avoid having to magnetise more than they need. Especially must they avoid having to magnetise the conductor if it consists of iron : hence in that case they cramp themselves tremendously into its outer skin, and thereby avoid having to overcome much more total impedance than they meet with in the case of copper ; but though they thus keep down impedance, they increase their dissipation of energy term, and get their oscillations damped out far more quickly than when they only have to pass through copper. The violence of the flash therefore subsides more quickly in an iron than it does in a copper conductor, and so I find it experimentally.

Nothing here said is in the least hypothetical. It is all absolutely clear and certain, and has been abundantly verified. I will not go into the history of the subject. It is well known.

27. Let it be clearly understood, once for all, that in comparing copper and iron conductors I never mean comparing them as of unequal thickness, *i.e.*, of equal conductivity. Such a comparison is ridiculous in the present state of knowledge. They are to be compared when of the *same* thickness ; and under those circumstances I assert iron to be a trifle better, certainly not a whit worse, than copper ; irrespective of all its other manifest advantages, cheapness, fusing-point, &c., &c. Want of flexibility is sometimes urged against iron, but stout telegraph wire is flexible enough ; and, until experience decides to the contrary, I feel sure it is thick enough for lightning conductors.

The one and only thing on which anything can be said against iron is on the subject of its durability, and this being a chemical question I offer no positive opinion ; at the same time I am absolutely certain that any slight disadvantage in that respect is a hundredfold compensated in most localities by its other superlative advantages.

Current and Potentials during Discharge.

28. In cases where a conductor is pretty thick, say, anything like a quarter inch diameter, or even a tenth, and of any moderate length, such as 100 yards or less (not many miles), the two terms of impedance are so unequal that it is for many purposes needless to think about R at all, the impedance is practically p L simply ; and this, as I have shown in *Phil. Mag.*, August, 1887, is under any given circumstances half the critical *resistance* which determines whether the discharge shall be oscillatory or not under the same circumstances. The total impedance is commonly to be reckoned in hundred or even thousands of ohms.

29. The strength of current passing in the alternations can be estimated by considering that the whole quantity stored up in the discharged body has to be transmitted in a quarter of one oscillation period—say, for instance, in the millionth of a second. If the quantity discharged were one coulomb this would mean a current of a million amperes. In any case the current must be hundreds or thousands of amperes.

30. The difference of potential needed to drive so strong a current through so great an obstruction is enormous, being equal to the product P C, and may be reckoned in millions or hundreds of millions of volts ; hence it is that lightning conductors afford no easy path for lightning, but that it tends to spit off in all directions, even to what would seem, and indeed are, very inferior conductors. It will spit off from a well-earthed stout copper rod to bits of wood and to perfectly insulated bodies.

Effects in the Neighbourhood of a Discharge.

31. Putting together the enormous electrostatic potentials existing at the different points of a conductor conveying a discharge, and the violent oscillation to which so strong a current is subject, we perceive how great must be both the electrostatic and the electromagnetic induction in all space anywhere near it.

These disturbances, thus rendered certain and accounted for, can easily be experienced experimentally. I proceed to relate a few experiments out of a multitude which I have made.

32. I took a considerable length of highest conductivity No. O electrolytic copper wire, kindly lent me by Messrs. Thomas Bolton and Sons, and arranging one end so as to be accessible to Leyden jars, &c., carried the wire up to a high gallery and then down to earth. Earth was made in several ways on different occasions : water pipes, gas pipes, hot-water pipes which ramified the whole building, outside gas mains, bars buried in ground ; but the most effective and, indeed, perfect return circuit could be had when wanted by connecting the end metallically with the outside coat of the jar, without any earth contact at all. When this direct contact was not made, the outer coat of jar had of course to be connected to earth also, in order to complete the circuit. Very often they were both connected to each other and to earth as well. It makes no essential difference ; whatever may be considered the most satisfactory method, that may be adopted, and the phenomena will go on just as well. They may be briefly summarised as follows :—

1. If the conductor pass within an inch or two of any uninsulated piece of metal, it gives off a violent side flash to it.

If the far end of the conductor is neither earthed nor connected to jar, but is left insulated in air, side-flashing from it occurs a trifle more easily, but not very markedly so.

2. If the conductor pass within, say, half an inch of an insulated conductor, it gives off a side flash to it ; the strength of the flash depends on the capacity of the insulated conductor, being considerable if it be large ; but some side spark occurs to an absurdly small body perfectly insulated, *e.g.*, such a thing as a coin on a stick of sealing wax, and this when the conductor is absolutely well earthed at its far end.

3. Sparks can be obtained from anything, even quite uninsulated things, connected to the conductor ; for instance, if it be connected to the gas pipes, small sparks will fly to the finger or to an insulated body from all the gas brackets about, and these sparks are sufficient to ignite gas.

4. Sparks can be obtained between the ends of any long curved conductor, be it insulated or uninsulated, if they are brought close enough together to form a nearly closed circuit.

5. Sparks can be obtained from or between insulated bodies in the neighbourhood of the conductor, and not connected to it at all, every time a flash occurs.

For instance, a large piece of wire gauze connected to nothing gave off sparks to a gas bracket and ignited the gas. Moreover, one piece of wire gauze sparked small sparks into another, neither connected with anything.

6. Sparks can be obtained from quite uninsulated bodies, even when not connected with the conductor, *e.g.*, from hot-water pipes, from gas pipes, from water pipes, from strips of brass let into the table, from gas brackets in other rooms, from a wire lying on the floor of a distant corridor ; and, in fact, all over the building, with few exceptions The sparks can be taken by a penknife held in hand ; sometimes they can be taken to the knuckle or finger-tip even when pressed against them.

7. Sparks can be got to pass between two totally uninsulated things, neither of which have any connection with the lightning conductor. For instance, let the conductor be thoroughly earthed in some outdoor and distant manner, and under favourable circumstances a bright short spark can be seen passing at every discharge between a gas tap and a water tap of my lecture table which happen to approach each other closely. Let the gas escape near these sparks and it ignites.

8. Sparks can be got between two thinly insulated electric-light wires if they lie close enough together, and if a storage battery be

Digitized by Google

connected to them an arc will be started, destroying the insulation and burning the wires.

9. If at any distant place, or out of doors in daytime, the sparks are too feeble to be seen, disturbances can still be easily detected by means of a telephone, connecting one terminal to the thing—say, the roof of a shed or a wire fence—and holding the other end in one hand; or, of course, by connecting the two terminals to two different things, or to different parts of one thing.

10. Arrange Abel's fuses between gas and water pipes, between pieces of wire gauze and gas pipe, between hot water pipe and a bit of sheet metal, between the lightning conductor and a 6in. metal sphere on long glass stem, between two large insulated bodies, between the gas bracket of another room and an empty Leyden jar; in short, in almost any place, likely or unlikely. Then take a few strong discharges through the thick copper rod with end well earthed, and the fuses will pop off, some at one discharge, some at another. Very visible sparks can sometimes be seen passing into the fuses, if they be not closely connected, without exploding them. A certain energy of spark is necessary to ignite the composition, much more than is sufficient to excite the retina.

Lightning Protectors.

33. Now let me say a word about the possibility of protecting telegraph and other instruments from damage by lightning currents which may have entered the aerial lines.

There is, indeed, no guarantee that burying wires beneath the pavement, or even beneath water, will effectually secure them from lightning disturbance, as I have now fully illustrated, but certainly overhead wires are more exposed.

The ordinary and well-known form of lightning protecting arrangement is to attach a pair of plates, or a double set of points, or a pair of points in a vacuum, or some other small air space, as a shunt to the instrument or coil of wire to be protected. Here are arrangements of the kind. Now it is perfectly easy to see that the protection such things afford is of the most utterly imperfect kind.

Take a coil of tangled silk-covered wire, or any other coil that you don't mind damaging, and attach it as a shunt to one of these protectors. On discharging a jar through it, the insulation of the coil is pierced in heaps of places. Or one may use a short fine wire, and see it deflagrated by the branch discharge.

34. It may be said that my air space is too wide. Very well, then abolish it altogether. Bring the plates of your protector into direct metallic contact. By so doing the coil is indeed shunted out of the circuit, and if it were a telegraph instrument no signal could be given, for no appreciable fraction of the current takes that route; but with a Leyden-jar flash it is otherwise. Although the plates of the protector are in contact, soldered together if one pleases, and led up to by stout wire or rod, a branch flash still breaks through the insulation of our wire tangle or deflagrates our little bit of thin wire.

35. It will be said the joints are bad. Well, then, do without joints; take a stout rod of electrolytic copper bent in an arc, say, 2ft. long, and bridging it across with the wire tangle, discharge a jar round it. Still a portion takes the thin wire, even though it offer a path yards in length.

Take a straight bar of copper an inch thick, and arrange an invisibly fine Wollaston wire of greater length as a tapping circuit. Some of the discharge shall leave the bar, and spark across a minute air gap at each end, in order to make use of the hair-like platinum wire.

Go further still than this. Connect a coil of thin-covered wire *by one end only* to a wire conveying a discharge, standing the reel upon a block of paraffin or other good insulator, and connect the other end to any little thing of any capacity at all—say, a bullet lying on the block of paraffin; you can see sparkings through the insulation of the wire on the reel at every discharge.

These experiments render manifest the hopelessness of any simple shunt arrangement as a lightning protector.

36. The easiest mode of exhibiting the essentials of these experiments—one that can be tried by any one possessing a Leyden jar, a pair of discharging tongs, and a yard or two of fine silk-covered wire—is to hang a tangle of the wire loosely on to the tongs, not necessarily making any sort of good contact, and then use them to discharge a jar in the very ordinary way. Some of the flash will take the thin wire and will spark through the insulation at a number of points.

37. It may be very well objected to me that it is pretty useless if I only point out the imperfection of present methods and offer no suggestion as to a proper lightning protector. Well, this struck me, too, and the result is that I have devised and made what I think I may call an absolutely perfect protector—one into which great flashes may be sent, and yet the galvanometer or instrument intended to be protected shall not wink, nor shall the slightest palpable or visible disturbance be discernible, notwithstanding that complete metallic contact is maintained all the time and not a trace of the signalling or useful current wasted.

The thing seems so good that I am making it the subject of a patent, and you will therefore pardon me for saying no more about it just yet.

38. The next part of this Paper is largely controversial. I do not take much pleasure in this portion, and wish it were unnecessary. But it is a purely impersonal controversy; and so long as the old-fashioned views are in existence, one way of arriving at the truth is to try and thrash them out of existence. If there is any real vitality in them, the attack will fail. It will be well believed that I have no feeling of hostility to the Lightning-Rod Conference when my best scientific friend, Prof. Carey Foster, was one of its members. Had I been one myself, I no doubt should at that time have signed the very documents which now, in a few places, I criticise. Had I indeed so signed, I would abuse what I now see to be its erroneous portions with still more vigour than I now permit myself to employ.

(To be continued.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, May 10th.

Royal Institution.

9 p.m. Evening Discourse. "The Optical Properties of Oxygen and Ozone." By Prof. Dewar, M.A., F.R.S.

SATURDAY, May 11th.

Royal Institution.

3 p.m. Afternoon Lecture. "The Origin and Development of Opera in England (with Musical Illustrations). By Joseph Bennett.

Physical Society.

5 p.m. (i.) "On an Electrostatic Field, produced by Varying Magnetic Induction." (ii.) "On the Concentration of Electro-magnetic Waves by Large Cylindrical Lenses." By Prof. O. J. Lodge, D.Sc., F.R.S.

MONDAY, May 13th.

Society of Arts.

8 p.m. Cantor Lecture VI., 2. "Heat Engines other than Steam." By H. Graham Harris, M.I.C.E.

TUESDAY, May 14th.

Royal Institution.

3 p.m. Afternoon Lecture. "The Italian Renaissance Painters: Their Employments." By Jean Paul Richter, Ph.D.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. Discussion on "The Treatment of Steel by Hydraulic Pressure, and the Plant Employed for the Purpose." By W. H. Greenwood, M.I.C.E.

Society of Arts.

8 p.m. Applied Art Section. "Venetian Glass." By Dr. Salviati.

WEDNESDAY, May 15th.

Royal Meteorological Society.

7 p.m. Ordinary Meeting. "Account of some Experiments made to Investigate the Connection between the Pressure and Velocity of the Wind." By W. H. Dines, B.A., F.R.Met.Soc. "On an Improved Method of Preparing Ozone Paper, and other forms of the Test, with Starch and Potassium Iodide." By C. H. Blackley, M.D., F.R.Met. Soc. "On the Climate of Akassa, Niger Territory." By Frank Russell, F.R.G.S.

Society of Arts.

8 p.m. Ordinary Meeting. "The Use of Spirit as an Agent in Prime Movers." By A. F. Yarrow.

THURSDAY, May 16th.

Royal Institution.

3 p.m. Afternoon Lecture. "Chemical Affinity." By Prof. Dewar, M.A., F.R.S.

Institution of Electrical Engineers.

8 p.m. Ordinary Meeting. Paper not decided on.

FRIDAY, May 17th.

Institution of Electrical Engineers.

8 p.m. Students' Meeting at 4, The Sanctuary, Westminster.

Royal Institution.

9 p.m. Evening Discourse. "Optical Torque." By Prof. S. P. Thompson, B.A., D.Sc.

SATURDAY, May 18th.

Royal Institution.

3 p.m. Afternoon Lecture. "The Origin and Development of Opera in England (with Musical Illustrations)." By Joseph Bennett.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 4 p.m.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

NOTICE.

Volume XXII. of "THE ELECTRICIAN," strongly bound in Cloth, is NOW READY. Price 12/6, post free, 13/6.

Cases for binding Volume XXII. are also NOW READY. Price 2/0, post free, 2/3.

The INDEX to Vol. XXII. is issued (Gratis) with this number of "THE ELECTRICIAN," and should be found in every copy. Complaints of non-receipt should be promptly forwarded to The Publisher.

Publishing Offices: 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
And at Manchester, Liverpool, and Glasgow.

"THE ELECTRICIAN" *can also be obtained of the* W. J. JOHNSTON COMPANY (LIMITED), "THE ELECTRICAL WORLD" *Office, Potter Building, New York, U.S.A.*

SPECIAL NOTICE.

With "THE ELECTRICIAN" *for May 17th will be issued a Steel Plate Portrait of the late* MR. C. H. B. PATEY, C.B., *Secretary for Postal Telegraphs.*

This number will be price **6d.**, *post free,* **6½d.**

A limited number of copies will be mounted on India Paper, and for these early application must be made.

Neat Frames and Mounts can be obtained on application to the Publisher.

X.X., 523.—*Letters await you.*

THE LIGHTING OF LONDON.

With the conclusion of the Board of Trade's Inquiry into the lighting of London, it is probable that the chief impression left upon the minds of our readers is one almost of dismay at the extraordinary complexity and magnitude of the problem which now confronts them. Whilst there is every reason to feel confidence in a successful issue, yet at the present stage we cannot overlook the fact that the Legal, the Technical, and the Commercial aspects of the question have each their own doubts and their own difficulties, and each involve considerations which not unfrequently appear to be in conflict both amongst themselves and with each other. Some of the responsibility for the existing difficulties must rest with the authors of the Electric Lighting Act, whose provisions are already discovered to be in many points incomplete, ambiguous, or inapplicable. There can be no doubt that it is a grave defect in the Act not to have distinctly specified whether an Order is or is not to be regarded as conferring a

Digitized by Google

monopoly within the scheduled district. In 1883 the Board seemed to take the view that a system of districting, and what is now described as "potential competition," was preferable to the actual existence of competing companies within one and the same area. With this view we are in general prepared to coincide; yet, on the other hand, the circumstances of different localities are so widely varied that we can well believe that occasions may arise when actual rather than "potential" competition will be distinctly for the public advantage. Since, however, the Act is admittedly inconclusive on this point, we do not see that the Board is under any necessity to pronounce a final or universally applicable decision either one way or the other. On the contrary, it would seem to be quite within its discretion to enforce a system of districting where such an arrangement would appear best suited to the locality, and none the less to permit a direct competition in neighbourhoods where the local conditions are of a different character.

Another proviso in which the Act is now seen to have been singularly deficient in foresight is that of the much controverted Purchase Clause. It seems strange that amidst all the strife and contention which has raged around this thorny question no one should have taken the trouble to inquire—until the London Electric Supply Company thought proper to furnish a concrete example—as to what should be done when the central station supplying current in a particular district happened to be situated in the domain of another local authority. The question now presented for decision amounts to this—whether at the end of forty-two years the Parish of Deptford is entitled, so far as this Act is concerned, to buy up plant capable of lighting the whole of London, and whether also the various Local Authorities to whom the Company in question may then chance to be supplying current are to content themselves with the questionable privilege of purchasing the local network of distributing mains. It is clear enough in practice that the system adopted by the London Company carries with it the entire abrogation of this section of the Act. But this certainly cannot for a moment be permitted to constitute a valid argument for refusing to sanction such a system. It would be a monstrous thing if the deficiencies and blunders of a legislative enactment were allowed to impose a veto upon the progress of engineering science, and to rule that no central station shall supply current beyond the limits of the Parish in which it may happen to be placed. And again, on the other hand, it must equally be admitted that the Local Authorities may justly consider it a grievance if their legitimate privileges are curtailed; and further, that competing companies may as reasonably complain if restrictions are imposed upon them from which others have succeeded in making their escape. The whole question affords a very pertinent illustration of the difficulties and absurdities which beset the application of doctrinaire legislation to a complex problem (ill-understood at best), whose conditions are in process of continual development with the advancement of science.

In yet another aspect of the problem we find ourselves confronted with a state of things little, if at all, contemplated in the Act, but in this instance the responsibility rests wholly with the Companies themselves. Possession, as we all know, is held to constitute nine-tenths of the law, and with one or two exceptions the Companies concerned have taken time by the forelock and have already gained a more or less precarious foothold within (or within reach of) the districts which they seek to light. The very fact that in this respect all are about equally guilty will tend somewhat to simplify the procedure of the Board. If one or two Companies alone had sinned the Inspector might conceivably have felt it his duty to uphold the stern majesty of the Law, and to enforce an awful warning upon all who might be tempted to the endeavour thus to force its hand. As matters stand he will possibly deem it sufficient to mark his appreciation of the correct and patient demeanour of the Notting Hill Company—which alone has done *absolutely* nothing—by granting everything it asks. Nevertheless, the question is not without its more serious aspect; and whatever may be the upshot of the London concessions, we take it that the Companies who work upon a wholesale scale will be ill advised if they attempt to pursue the same methods in many of the provincial towns. On the other hand, where local companies have been formed, and possess the assent of the Corporation, there would seem in general to be no sufficient reason why they should not push on (at least with the Central Station work) pending their applications to the Board.

Turning to the financial aspect of affairs, we have taken the opportunity to tabulate below some of the chief financial details which were elicited in evidence or have since been furnished us. It will be seen that the information solely relates to the

THE LONDON ELECTRIC LIGHTING COMPANIES.

Name of Company.	Registered Office.	Authorised Capital.	Paid-up Capital.	Expenditure incurred or Capital Allocated.	Remarks.
		£	£	£	
Chelsea Electricity Supply Company.	37, Sloane-square, S.W.	100,500	33,085	30,000	It is proposed to increase the capital to £205,000.
Electrical Power Storage Company.	4, Great Winchester-street, E.C.	200,000	149,500	—	It is proposed to raise £60,000.
House-to-House Electric Light Supply Company.	117, Bishopsgate-street, E.C.	350,000	41,600	—	—
Kensington & Knightsbridge Electric Lighting Company.	High-street, Kensington, W.	250,000	37,240	65,000	It is proposed to call up shortly an additional £30,000.

Westminster Electric Supply Corporation.	28 Victoria-street, W.	100,000	8,000	50,748	—

Digitized by Google

nine Companies who are now making application for Provisional Orders for the lighting of the Metropolis. The total authorised capital of these nine Companies is no less than £2,950,000, of which £1,033,157 has been already paid up. Two of the Companies, however—the House-to-House and the Electrical Power Storage, who possess between them a paid-up capital of £190,000—have work in hand besides the lighting of London. If a deduction be made on this account it will be seen that somewhere between £700,000 and £800,000 is actually invested at the present moment in central station work within the Metropolitan area. But this figure scarcely represents the true state of the case, for out of the authorised capital of £2,950,000 a sum considerably exceeding one million sterling has already been expended or allocated to specific work. The figures cannot at present be more precisely given, since, for reasons which will be obvious, some of the details are unattainable. The facts stated will, however, be sufficient to emphasise the assertion that capitalists have ceased to regard the electric light as a hopeless venture, and are now prepared to find funds for schemes of asound and well-considered character.

ELECTRIC LIGHTING AT THE MELBOURNE CENTENNIAL EXHIBITION.

At a time when we in this northern hemisphere are preparing to open our summer Exhibitions we have received the account of the close of the very successful Exhibition at Melbourne in Victoria, and, as part of its great success has been unquestionably due to the admirable way in which the electric lighting of it was carried out, we gladly print the account of it which we have received from the secretary of the Australasian Electric Light, Power and Storage Company. The commercial and technical details given are very full, and will be of value to our readers :—

The very short time allowed for the execution of the contract added materially to the contractor's difficulties and expenses ; but notwithstanding all obstacles the lights were in operation on the opening night and were well maintained until the close of the Exhibition, the number being constantly increased as fresh demands were made on the installation. The Exhibition was formally opened on the 1st August, but the contract was not signed until March 27, and the special annexe for the engines and dynamos was not ready until long after the date exp cted; while the month of July was more than half over before the painting of the inside was finished sufficiently to allow the cables and leads to be joined up to the dynamos and switchboard.

When the lighting of the Exhibition was first discussed, the question arose as to whether gas or electric light should be adopted. As concerned the picture galleries, there could be of course no question at all, as the sole condition on which many of the pictures were allowed to be exhibited at night was that they were not to be exposed to the fumes of gas.

Mr. K. L. Murray, of the Railway Department, who had extensive experience of lighting by gas and by electricity, was requested by the Commissioners to report on the matter, and his estimate, although made in November, 1887, was, as the figures which we give will show, wonderfully near the amount of lighting that was actually required. He estimated for 950 arc lights of 1,000 candle-power each and for about 50,000 candle-power other lighting, making a total of about 1,000,000 candle-power.

In Mr. Murray's report he stated that he considered it fair to compare gas and electric lighting at per candle-power, and doubtless many good reasons can be advanced for taking this as a fair ratio of comparison in a place like an Exhibition, and for the following reasons :—Firstly, as regards the portion lighted by arc lamps, the experience gained in the best lighted modern Exhibitions proves that not less than one candle-power must be allowed for each 1 to 1½ square feet of floor surface if the building is to appear bright, cheerful, and attractive at night ; or, in other words, that one must allow from ·66 to 1 candle-power for every square foot of floor space. This proportion was confirmed by experience at the Adelaide Exhibition, at which it was found that although 1 candle-power per 1·44 square feet gave a good light when the space was open and the colouring of the locality light, yet the same amount of candle-power produced but a gloomy effect among crowded show-cases and where the surroundings were of a dark tone. In adopting the above figure it must distinctly be borne in mind that although 1 candle-power per square foot of floor surface, or even more, may be provided by the installation, it by no means follows that there will be 1 candle-power of light per square foot *on the floor* of a building, as much of the light goes sideways and upwards.

Mr. Murray's estimate assumed the use of burners consuming 5 cubic feet of gas per hour with gas at 5s. 9d. per 1,000ft., and that each of them would give 20 candle-power. Only best gas and Argand burners would yield such an average, whereas in the Centennial Exhibition the bat's-wing or fish-tail burners must have been employed. Gas is, however, 5s. 4d. per 1,000ft. in Melbourne now, and, although it was dearer when the Exhibition started, it may be taken for granted that an average of 16 candle-power for a 5ft. burner with Melbourne gas is a liberal allowance even when the pipes keep clear, which rarely happens for any length of time. Now the total area to be illuminated in this case by arc lamps was 1,142,821 square feet, and to light this area 915 such lamps were used with actual illuminating power of 924,000 candles ; consequently the average area illuminated by each lamp was 1249·9 square feet of floor space, or ·808 candle-power per square foot.

To give the same amount of light by gas would have required about 58,000 No. 5 burners with their numerous adjuncts, which would consume 290,000 cubic feet of gas per hour at 5s. 4d. per 1,000ft., or at a cost of about £78 per hour. The expense of fitting up this mode of lighting would have been heavy ; but against that may be set the cost of the special building erected for the electric dynamos, engines, &c. The accounts are not yet closed, but the latest available printed figures reveal that the cost of the whole of the installation plant, including incandescence dynamos and all accessories, has been £60,000. As the special building is set off against gas-pipes and fittings which would afterwards be almost valueless, the whole of the plant is saleable ; but allowing 50 per cent. for depreciation and other contingencies, it is found that the use of the electric plant has necessitated an expenditure of £30,000, exclusive of six months' interest at 5 per cent., to which must be added the cost of 26 weeks of working. The correctness of the figures cannot absolutely be vouched for, but an amount of £300 it is believed will give a little over the actual cost of the fuel, wages, carbons, &c., for arc lighting.

We thus have the following results :—

Net cost of plant	£30,750
Cost of working for 26 weeks at £300 per week	7,800
Actual cost of electric arc lighting	£38,550

In these figures the arc lighting is considerably handicapped by including the cost of the incandescence plant, which means engines, dynamos, and lamps nightly supplying 44,112 candle-power = 2,757 other No. 5 gas burners in situations where gas would be intolerable.

There were 160 nights of lighting (783½ hours) ; consequently the nightly average was 4·89 hours, which, at £78 per hour, gives £331 per night, or £53,429 for the term of the Exhibition, as the gas bill for those portions lighted by arc light, showing a clear saving of £15,000 in favour of the electric light. The volume of heat which so many gas jets would have emitted would have been enormous, and both the picture galleries and the concert hall would have been intolerably close if gas had been used.

Mr. K. L. Murray drew up the specifications, and to the constant and careful supervision by himself, and by his assistant, Mr. W. Stone, much of the success of the scheme is due.

Tenders were originally put in by the Australian Electric Company, Melbourne, as agents for the "Australasian Electric Light, Power and Storage Company, London," carrying on business in these Colonies.

Captain F. C. Rowan, General Manager of the Australasian Company, assisted by Mr. R. E. Fletcher as Chief Engineer, prepared the estimates and ordered the plant. The latter was nearly all supplied by the Anglo-American Brush Corporation, and all parties concerned in the enterprise deserve great praise for the rapidity and completeness with which this, the largest and most important electric light installation yet carried out, was placed in good working order and successfully maintained, despite the unlucky accident to the R.M.S. "Garonne" while on her way out with a large portion of the plant, which compelled the contractors to work for some time, both night and day, and involved a serious charge for overtime.

The following statistics in this connection will be of interest :—

Total area of buildings lighted by arc lamps	1,142,821	sq. ft.
Total area of buildings lighted by incandescent lamps	163,906	,,
Number of Brush arc lamps used in building	908	937
Number of Brush arc lamps used outside of building	29	
Number of Brockie-Pell arc lamps used	5	
Total number of arc lamps	942	
Number of Edison-Swan incandescence lamps, 16 candle-power	1,882	
Number of Sunbeam incandescence lamps of 200, 300, 400, 500, and 600 candle-power	27	
Total candle-power of arc lamps	953,000	
Total candle-power of incandescence lamps	44,112	
Average area of floor space per arc lamp (915 lamps) inside lighting	1249·9	sq. ft.

Digitized by Google

Average area of floor space per incandescence lamp	85·9 sq. ft.
Candle-power per square foot of floor space (arc lights) inside lighting	·808 c.-p
Candle-power per square foot of floor space (incandescence) inside lighting	·268 „
Total number of hours lighting	783½ hrs.
Average number of hours per night (160 nights)	4·89 „
Total number of watts used by arc lamps, inside lighting —447,696. Ditto, outside lighting—14,123	461,819
Watts per square foot of floor space (inside lighting) ...	391
Total number of watts used by incandescence lamps —1882—16 candle-power 64 watts = 120,448 watts, 27 Sunbeam = 24,295 watts	144,743
Watts per square foot of floor space	383
Area of concert hall	19,000 sq. ft.
Candle-power of incandescence lamps in Concert Hall ...	·578 c.-p. per „
Circuits (Arc)—Number of arc circuits	41
Average length of circuits	1·22 miles
Total amount of cable used	50 „
Incandescence—Number of incandescence circuits.....	7
Amount of main cable used	3m. 981yds.
Amount of Brush mains and leads to arc lamps	10 miles
Total amount of cable and wires used for arc and incandescence circuits	63m. 981yds.
Total weight of copper in above	17tn. 11cwt. 1qr. 19lb.
Dynamos (Arc)—1 No. 8 L Brush dynamo, 55 lamps ...	27,500 watts
40 No. 7 L Brush dynamos, 24 lamps = 12,000 × 40.....	480,000 „
1 No. 6 Brush dynamo, 10 lamps	5,000 „
Total capacity or out-put available from arc dynamos (=1,025 Brush lamps)	515,000 „
Incandescence—7 No. E 2 Victoria dynamos, 110 volts, 210 amperes	23,100 „
Total capacity of above machines in 16 candle-power 64-watts lamps	2,526 lamps
Belting—Lancashire patent woven belt	3,452 feet

Shafting—Total length, 203 feet.
Diameter, 7½ to 6¼ inches.
Supported on 33 iron pedestals.
Divided into three sections, with clutch couplings, but always run connected as one length.
Fitted with 52 pairs of cast-iron pulleys (one fast and one loose of each pair), for driving the arc and incandescence dynamos.
Normal speed of shafting, 192 revolutions per minute.

ENGINES.—Three pairs of horizontal high-pressure engines of Marshall and Sons' type, with automatic expansion gear.

Each pair fitted with a cast-iron fly-wheel 12ft. diameter, weighing 19 tons, and having 13 grooves on face for 13 = 4½in. manilla ropes, 12 ropes used for driving on to counter-shaft.

Diameter of cylinders, 20in.

Length of stroke, 40in.

Normal speed, 60 revolutions per minute, but worked up to 80 revolutions.

Normal horse-power of each pair, 500 horse-power.

BOILERS.—Twelve boilers of the Cornish multitubular type 16ft. 9in. in length by 5ft. 9in. in diameter, furnace tubes 10ft. 10in. in length by 3ft. 3in. in diameter, and 148 tubes 2in. outside diameter and 5ft. 11in. in length.

Each boiler provided with cylindrical steam chamber on top, and the whole covered with wrought-iron casing, forming a portion of the flues, and acting as a super-heater for the steam.

All boilers fitted with double safety valves of the Ramsbottom type, 3in. diameter, and the usual gauge-glasses, blow-off cocks, &c., and rest in cast-iron saddles; the lower and unprotected portions of the boilers are covered with a non-conducting heat composition. The boilers are arranged in two groups of eight and four, and are in separate houses. They are all connected to one common steam main, each boiler being provided with a steam stop-valve, to disconnect from the main if required.

Working pressure, 120lb. per square inch.

Six-inch Blake's donkey-pumps and 6-in. Gresham's patent improved Gifford's injectors supplied the water to the boilers, after passing the water through 6 feed-water heaters, which raised its temperature to 170 and 180 deg. Fah.

Three wrought-iron smoke-stacks, 3ft. 9in. diameter, carried away the smoke, of which, however, there was very little, as the fuel consisted of coke with a very small quantity of coal mixed with it.

Boiler-houses, engine and dynamo-room were all under one roof, the boiler-houses being separated from the engine and dynamo room by brick walls.

Total length of dynamo-room, 221ft.

Total width of dynamo-room, 142ft. 6in., less 47ft. 6in. occupied by engines and boilers.

Arrangements of Dynamos and Circuits.—The dynamos were arranged in two parallel rows on each side of the counter-shafting, which was in the centre of the room.

The arc dynamos were connected to a switch-board of simple construction, to which also all the ends of the various lamp circuits were connected. By this arrangement any dynamo could be put on to any lamp circuit as desired.

The lamp circuits were arranged so that in every court in the vast building the lamps lighting a particular court were supplied with current from separate dynamos, which prevented the possibility of any part of the building being left in darkness should any mishap occur with the machinery.

The incandescence dynamos were connected to a very elaborate and handsome switch-board, by means of which all the dynamos could be joined up in parallel.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

SECTION III.—MAGNETIC FIELDS OF COILS AND SOLENOIDS.

(*Continued from page 711.*)

Let us now apply this to the numerical example given above. The length of R will be seen to be the square root of the sum of the squares of the mean radius and length of the solenoid, which are two and six centimetres respectively. Hence

$$R = \sqrt{4+36} = 6{\cdot}32 \text{ centimetres.}$$

The current is 3 amperes (or ·3 C.-G.-S. units), and the number of turns of wire 200; therefore the field at either end of this solenoid is equal to

$$\frac{2 \times 3{\cdot}1416 \times {\cdot}3 \times 200}{6{\cdot}32} = \frac{377}{6{\cdot}32} = 59{\cdot}6 \text{ C.-G.-S. units.}$$

Now suppose we take a solenoid (Fig 150) exactly double the length of the above, but in all other respects the same, that is having the same depth of winding and the same

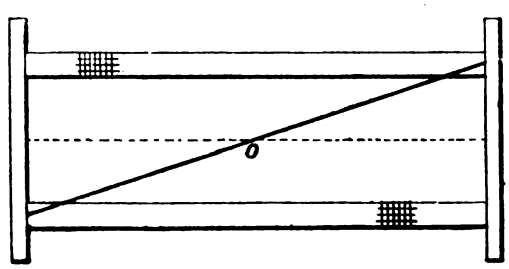

FIG. 150.

current. Evidently the field at the point O, taken now at the centre, will be twice that at the end of the former solenoid, and therefore we can write it down at once as

$$4\pi C_1 \times \frac{l}{R} \text{ C.-G.-S. units.}$$

But l is now only half the length of this solenoid, and therefore it is advisable to multiply both l and R by 2 (which does not alter their ratio). Now the value 2 R is equal to the line connecting opposite corners of the solenoid (Fig. 150), which we will distinguish by calling it the diagonal (D). And instead of writing $2l$ for the length of the present solenoid we shall write it l, keeping this letter to represent the length of solenoid whatever it may be. Therefore the field at the centre becomes

$$4\pi C_1 \times \frac{l}{D} \text{ C.-G.-S. units.}$$

Now let C^1 (the current per unit length) be expressed in terms of C (the current passing through the wire). It will be understood that the current per unit length of coil is the same value as before, and is expressed by the total current flowing round the bobbin (Cn) divided by l, n being the number of turns and l the length of the present solenoid. Cancelling out l the field at O becomes

$$\frac{4\pi Cn}{D} \text{ C.-G.-S. units.}$$

This is applicable to any dimensions of solenoid, and gives the field produced at the central point on the axis where it is most frequently required to be known.

Digitized by Google

We have now the means of determining the strength of field at either end of a solenoid and at its centre on the axis. It will now be understood that taking *any* size solenoid whatever, and denoting by the letters R and D the two lines drawn and so marked in the figure (Fig. 151), that the field at either end on the axis is equal to

$$\frac{2\pi C n}{R} \text{ C.-G.-S. units.}$$

and that at the centre is

$$\frac{4\pi C n}{D} \text{ C.-G.-S. units.}$$

It is worthy of note that when the solenoid is very long R becomes practically equal to D, while if the solenoid is very short, more like a galvanometer coil, R is practically equal to half of D.

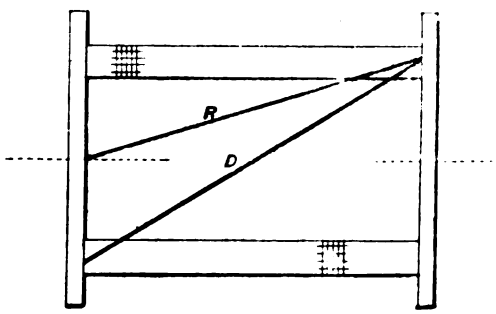

Fig. 151.

Applying the latter expression to find the field at the centre of the solenoid whose dimensions are given above (Fig. 148), we find that the numerator is twice the previously calculated amount, and is therefore equal to 754. The length of D is the square root of the sum of the squares of the mean diameter

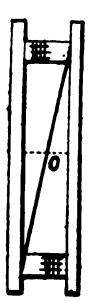

Fig. 152

and length of solenoid, which are 4 and 6 centimetres respectively. Hence

$$D = \sqrt{16+36} = 7{\cdot}21 \text{ centimetres,}$$

and the field at the centre is therefore equal to

$$\frac{754}{7{\cdot}21} = 104{\cdot}5 \text{ C.-G.-S. units.}$$

It will easily be seen that the *longer* the solenoid the nearer does D become equal to l, and that for a long narrow solenoid we may consider it the same as l without any appreciable error. The field at the centre of such a solenoid is then—

$$\frac{4\pi C n}{l} \text{ C.-G.-S. units,}$$

to which expression reference has already been made (paras. 130 and 133). Again, the shorter the length of the solenoid the more it approaches the shape of a current ring (Fig. 152), and we should therefore expect the field at the centre to become very nearly equal to that due to a thin ring of current. This is so, for the diagonal line is very nearly the same as the mean diameter of the coil, and does become exactly equal to it when the coil is made shorter and shorter till it forms a narrow ring. When such is the case, instead of the diagonal D in the above expression we can put the mean diameter of the coil or twice the mean radius ($2r$). Cancelling out the 2, the field at the centre becomes

$$\frac{2\pi C n}{r} \text{ C.-G.-S. units,}$$

which is the same as previously derived for a narrow ring-shaped coil of n turns (par. 145).

The next point to consider is the strength of field at *any* point on the axis either inside or outside the solenoid, and this case will necessarily include those already taken. The expressions, however, which have been derived above for finding the field at the centre and at either end of a solenoid will be found useful not only as steps leading up to the most general case, but as easy expressions to deal with, showing also at a glance the relation between the field at these points and the diameter, length, and depth of winding of a solenoid.

(To be continued.)

THE BOARD OF TRADE INQUIRY ON THE LONDON ELECTRIC LIGHTING PROVISIONAL ORDERS.

This Inquiry was concluded on Wednesday, 1st inst. Our last report of the proceedings was brought up to the end of the previous Monday. The following gentlemen represented the various parties concerned :—

Mr. Pember, Q.C., Mr. A. K. Loyd, and Mr. J. C. Graham appeared for the London Electric Supply Corporation ; Mr. C. A. Cripps for the Metropolitan Electric Supply Company ; Mr. Moulton, Q.C., and Mr. R. S. Wright for the Chelsea Electricity Supply Company ; Mr. Muirhead for the St. James's and Pall Mall Electric Light Company ; Mr. Roger W. Wallace for the Notting Hill Electric Light Company, for the Kensington and Knightsbridge Electric Lighting Company, and for the Westminster Electri-Supply Corporation ; Mr. Moulton, Q.C., and Dr. Hunter, M.P., for the Electrical Power Storage Company ; Mr. G. Prior Goldney (the City Remembrancer) for the City of London ; Mr. T. Percy Gunyon (engineer) and two members of the Council for the London County Council ; Mr. C. A. Cripps and Mr. F. M. Jenkins for the Strand District Board of Works ; Mr. Hopwood (solicitor) for the Holborn District Board of Works ; Mr. E. Bayley (clerk) and Mr. G. W. Thompson (surveyor) for the St. Olave's District Board of Works ; Mr. James Spencer for the Greenwich District Board of Works ; Mr. J. H. Horton for the Paddington Vestry ; Mr. Hitchins for the St. George's (Hanover-square) Vestry ; Mr. Wilkins (clerk) and Mr. W. Jenkins (chairman of the Lighting Committee) for the St. James's (Westminster) Vestry ; Mr. Webster Murnane (clerk) for the St. Martin's-in-the-Fields Vestry ; Mr. T. Eccleston Gibb (clerk), and Prof. Robinson, C.E., for the St. Pancras Vestry ; Mr. Cripps and Mr. Greenwell for the Marylebone Vestry ; Mr. H. J. Smith (clerk) for the Lambeth Vestry ; Mr. Harrison (solicitor) for the Bermondsey Vestry ; Mr. E. Moore (solicitor) for the Great Eastern Railway Company ; Messrs. Payne, Son and Pollock (solicitors) for the North London Railway Company.

Tuesday, April 30.

Mr. C. A. CRIPPS, continuing his speech on behalf of the Metropolitan Company, said there were only certain preamble objections, if he might so call them, to his Mid-London Order. They came from St. Margaret's and St. John's, Westminster, from the City, and to a certain extent from the St. Giles's District Board of Works. With those exceptions there was no opposition from any local authority in respect of any of the orders asked for under the Mid-London Order. Now the attitude taken up by the St. Margaret's and St. John's, Westminster, is this : they say "We think all Provisional Orders should be refused, and that the local authority should be allowed another year to consider the whole question." As no evidence was given on behalf of the Vestry he did not know why objection was taken, nor did he know whether he could deal with that objection in matters of detail or drafting. But the Vestry had stated, and stated specifically, that if any Order is granted they are in favour of competition ; as, therefore, the competitors in the parish were the London Company, the Metropolitan Company, and Mr. Wallace's Company, he could only plead in reference to this local authority that if any Order is granted it should assuredly be given, amongst others, to the Metropolitan Company. With regard to the City objection there can be no doubt that the City is placed on precisely the same basis as all other local authorities with powers in the schedule to the Act of 1882. It is quite right, no doubt, that the wishes of the City should be considered and consulted, but whatever their powers may be, or whatever the powers of the Commissioners of Sewers may be under the Act of 1848, it is quite clear as regards electric lighting they are on the same basis as all other local authorities.

Mr. RUSSELL GRIFFITHS : That is not so. They have greater powers.

Mr. C. A. CRIPPS said his argument was they were under the Electric Lighting Acts. As regards the objection of the City to the system, he

Digitized by Google

would say without hesitation that every criticism which had been advanced by Mr. Russell Griffiths was not against the Metropolitan but against the London; there was not one suggestion of electrical difficulty brought forward which was applicable to the Metropolitan Company. He would submit that, having modified the 21 years back to the 42 years, and taking Mr. Preece's own opinion that the converter system with central stations is the best for the City, and taking, further, that the Metropolitan were willing to go into the City, not on the competition system but on the districting system, there is no difficulty between the Metropolitan Company and the City which can keep them apart. He believed negotiations had already begun, and he hoped they would soon be consummated, to the immense advantage of the City and to the advantage also, no doubt, of the Metropolitan Company, who had laid out an immense amount of money and arranged for stations so as to deal with the City as well as with other places in respect of which they ask for Orders. He now came to what was no doubt a very controversial matter—the Strand agreement. It had been attacked by two bodies—the London Company and the St. Giles's District Board of Works; but it had been attacked on entirely inconsistent lines. Mr. Pember, for the London Company, urged that it was an improper agreement, an agreement which could not be sanctioned by the Board of Trade, and that it was contrary to the policy of Parliament as shown in the Electric Lighting Acts. Mr. Jones, for the St. Giles's District, took an entirely different attitude. He said that it was a very proper thing for the local authority and the company to come to these terms, that they were very proper and admirable ones; but he said, "If you give these terms to the Strand why do not you give similar terms to the local authority which I represent." There had been a suggestion of unfair advantage shown to the Metropolitan Company. Now the evidence came to this: That originally a letter was sent in identically the same terms to the London and Metropolitan companies; that that was followed by negotiations with both Companies; that as regards the London Company the negotiations came to nothing; that as regards the Metropolitan Company the negotiations ultimately ended in the agreement which was now before the Inquiry, and the only possible suggestion of unfairness of any kind was that the Strand Board of Works did not disclose to the London Company the terms on which they were negotiating with the Metropolitan Company. He would say without hesitation that it would have been an improper thing for the Strand Board of Works to have done so. The Metropolitan did not ask to see the London negotiations, nor were they disclosed to them. Where, then, was the unfair advantage? Going through the paragraphs of the agreement, the first deals with appropriation of stations. What was there contrary to any proper negotiation as between a local authority and the company that there should not be an appropriation of stations for the purpose of the particular district? The second paragraph is with regard to the distributing of electric lines, which he thought was a very proper thing for the local authority to determine. The third is "distributing boxes," and he thought it was a proper thing for the District Board to decide where they should be put. Now the obligation to supply is next. The effect there is that somewhat better terms are given to the consumer than under the ordinary forms of Provisional Orders—what was there immoral or wrong in that? Then the "normal pressure" clause. The alteration there brings the normal pressure within the cognisance of the Board of Trade and is fixed by penalties, and there could not be any question that that was a matter properly dealt with by the agreement. The sixth is the "additional facility" clause. That is nothing more than, whereas under the old Orders they had Schedule A and Schedule B, here after a certain time other streets and other districts are to have the same facilities as the streets marked green upon the plan. The seventh is interference with the surface of streets; it was a matter which had been fought over and over again in Parliament, and been decided sometimes one way and sometimes the other. He could give fifty precedents for it. Then there remained the last—the question of price. To show the *bonâ fides* as to that he would say they had taken the price in the Order. As to revision of prices, he maintained that it was a perfectly proper thing that in an agreement extending over forty-two years there should be revision of price. There were many questions still to be worked out with regard to the systems of lighting and with regard to cost, and it was a perfectly proper thing that from time to time there should be a revision of the price. In the early Gas Acts there was revision of price; he knew it had been superseded by the sliding scale, but he said the sliding scale in itself was a revision of prices—the very essence of the sliding scale was a revision of prices—and it had been going on in the Metropolis to the very great advantage of both the consumers and the companies. How his friend could say in the face of the sliding scale doctrine that the revision of prices is improper he was at a loss to understand. The Inspector clause, it appeared to him, in no way infringed upon the proper authority of the Board of Trade. Then "additional mains to be laid in the street, and the manner in which requisition is to be made, and the provisions for requisition," were, it appeared to him, purely domestic matters, to be settled between the local authority and company, whatever it may be. Then "Provision for requisition by the District Board"—well, that gives the District Board favourable terms—that was what that came to. Then there comes "damages for default," which his learned friend suggests are heavy. Well, let them be heavy; let them be such as the London Company could not face. The Metropolitan did not fear. The supply clause is a mere matter for the consumer. The maximum current clause is taken out because it is absolutely the same as in the Provisional Order—there is no difference between the two. Then the question of supply of electricity to public lamps—that is certainly a matter which comes within the cognisance of the local authority. With regard to the clause as to termination of agreement, the effect of that is that if the Metropolitan do not do their duty it is brought to the notice of some independent gentlemen appointed by the London County Council, and if they decide that they had not done their duty then they would lose the benefit of their Order.

Major MARINDIN: What I understand is simply this, that under the Order the power of revocation is in the hands of the Board of Trade, and here it is in the hands of the London County Council.

Mr. PEMBER: They have got two chances of being turned out—one if the Board of Trade thinks they ought to be turned out, and one if the District Board independently thinks they ought to be turned out.

Mr. CRIPPS said the District Board act not directly but through the medium of an arbitrator appointed by the County Council. He submitted with great confidence that there was no inconsistency in the two provisions. The only other point he thought he need refer to was with reference to the appointment of an arbitrator at the termination of the agreement. He was anxious that it should be left to the Board of Trade and not to the County Council, but it was a matter on which no doubt both parties would be very much influenced by any statement that the Inspector might make with regard to the Board of Trade. Now, leaving the Strand agreement, he would deal shortly with a matter which affected all the Orders, and that was the clause which Mr. Moulton suggested on behalf of the telephone companies. Mr. Moulton's argument was this: you are creating a nuisance, and being parties creating a nuisance you must for all time protect any one who may be affected by the nuisance which you are creating, and therefore not only as regards existing telephone wires but as regards all telephone wires which may be laid down in the future you must come under terms to provide against all possible or contingent damage. Now he (Mr. Cripps) said as a matter of principle that argument was quite wrong—it was a monstrous assumption. The right principle was this—and it was a principle that had been adopted over and over again—that where a telephone company have laid down their system and are in occupation they have a right to be protected against any second company seeking to come in. Where they are first in possession they are entitled to the rights they have got, and if we interfere with those rights we ought to give them full compensation. Where we are first in possession we are entitled to be protected in exactly the same way. Mr. Cripps said he would now deal with the question of the comparison of systems. If the alternating current could not be used for motors that was an advantage for the purposes of this Inquiry, as all the company's capital must then be devoted to lighting; but he said that motors could be used, and they had their hands free to use the direct system for motors.

Major MARINDIN: I do not agree with you that we are dealing with lighting only. I cannot take that.

Mr. C. A. CRIPPS said that scientific gentlemen were of opinion that the alternating system could be used for motors. In the system of the London Company he contended that there were numerous difficulties which Mr. Ferranti had not disclosed how he intended to overcome. The London Company had attacked the Metropolitan system, and, therefore, he must call attention to the weak points in their harness. They had not had a single expert to back up Mr. Ferranti. He thought there was an overwhelming preponderance of the best scientific opinion in favour of the alternating system as proposed by the Metropolitan Company.

Mr. PEMBER said that the Metropolitan and the London cases were undoubtedly the most important of the Inquiry. It was the unpledged companies who desired to shut out the competition of the London Company. As to compulsory areas, they were admirable things to prevent a company with only problematical chances of getting its capital grabbing a district and keeping others out. The London would spend the whole of the £800,000, or more if wanted, to supply the districts it had undertaken to serve. If at the end of the 42 years the local authority bought up the undertaking without the Deptford Station, the Deptford plant would remain on the hands of the company, but he was not at all afraid of such a contingency. The Deptford Station would avoid the addition of 1,000 tons of coal cartage a day in the Metropolis, and that enormous cartage meant serious addition to the wear of the roads. Then as to the repair of batteries at the stations proposed in London, that either meant additional cartage and traffic or noise at the stations during repair, so that absolute quiet would not reign even at the Storage Company's proposed stations. A moderate-sized room, on the other hand, would suffice for the distributing stations of the London company. That was all the London company intended to do in the way of setting up buildings in London. Mr. Moulton had said that there would be "darkness if one gigantic dynamo went wrong." How could there be when there were two? The reduction of the voltage from 10,000 to 2,400 was not a question of experiment, but was actually done at the present time. Now their system, apparently so complete and simple, was by far the newest and the greatest stride taken in practical electricity for many years. Gentlemen had been loud-tongued on short-circuiting and its consequences, the difficulties of jointing on the voltage of 10,000, on leakage from primary and secondary mains, the injurious effects of transformers on the life of lamps, and the absence of a motor for the alternating current—this was a long list of objections which he would deal with on the next day.

Wednesday, May 1.

Mr. PEMBER, resuming his address on behalf of the London Electric Supply Corporation, commenced by stating that he had been told that Major Marindin had stated at Brighton the other day that the Board of Trade had determined not to adopt the new unit.

Major MARINDIN said that that was so.

Mr. PEMBER said that oddly enough in a journal which had been shown to him it was stated that the Board of Trade had made up their minds to adopt the new unit.

Major MARINDIN said he was informed by the Board of Trade that they had decided to retain their own unit and not to adopt the new unit.

Mr. PEMBER said no doubt Major Marindin was better informed than the journalist in question; but he urged that they should adopt the larger unit of 10,000 amperes, as in the schedule of the London Company, rather than that of 1,000 amperes—for this reason, that with the price at 7½d., as at present charged at the Grosvenor Gallery, the smallest reduction which they

Digitized by Google

could make in the charge would be ¼d., that being the smallest coin of the realm, and that would represent a reduction of 3 per cent., whereas in the case of a gas company, with the unit of 1,000 cubic feet, and a charge at 3s. 2d., the reduction was not of such a serious consequence. He would now proceed to deal with the objections which had been raised to what, *primâ facie*, seemed so admirable a system, namely, that of keeping the manufacturer outside London, and bringing the article wanted along trunk mains into town, and there, by small distributing stations, and without any moving machinery at all, distributing it amongst the various customers. It was impossible to conceive any simpler method, or, *primâ facie*, a better system for a great city like London. The objections that had been raised constituted every objection which hostility or self-interest or ingenuity could raise. The first objection was under the head of short-circuiting, which of course was connected with the joint. But Mr. Ferranti was not at all afraid of that, for his mains had been tried at 1,000,000 volts, and although that was not proof positive that the joint would stand the requisite test, yet that gave a margin of 100 to 1 for the pressure of 10,000 volts at which the electricity would pass. But experiments had been made from day to day while the Inquiry had been going on, and the Board of Trade would be informed that Mr. Ferranti's joints had been tested on the previous day only and found to stand a pressure of 650,000 volts.

Captain CARDEW: Many?

Mr. PEMBER: One joint. No doubt Captain Cardew would satisfy himself on the point, but he felt he would not be justified in withholding the information, although it was not strictly evidence. Dealing with Mr. Preece's evidence, he said that gentleman was called against him by the City, but they could hardly have known what Mr. Preece's opinions really were. When asked if the proposal of the London Company to supply from Deptford was a reasonable proposal he might have said "No;" but he did not say so, but merely that it was a gigantic experiment, and simply a question of pounds, shillings, and pence. And even on the commercial point he was not against the system of the London Company, though he was certainly in favour of the alternating system with the transformer. His objection was to the connection between London and Deptford by means of their mains, but everything else he admitted was perfectly workable. His objection related simply and solely to the way in which the company brought their mains up to London and the question of insulation and earthing, and when requested to formulate his objection he said that the difficulties he anticipated were difficulties of insulation of joints and of disturbance of the telegraphs and telephones. The company were willing to meet the objections of the Post Office and the question of safety to the public, and experiments were going on for that purpose. But the most important admission was that a cable could be made which should carry the main from Deptford to London, which would get rid of the Post Office objections and yet ensure the safety of the public. That, he thought, was absolutely conclusive. He did not wish it to be imagined that he was vain enough to wish to triumph over Mr. Preece, for if that gentleman had not felt what he said in the unqualified way in which he said it he would have thrown him (Mr. Pember) on his back in two minutes, and Mr. Preece was not a man whom he would cross-examine, in the hostile sense of the word, in such an inquiry as the present, but he insisted that the ultimate result of his evidence was uncommonly in favour of the London Company. Dr. Hopkinson, dealing with the question of electrostatic induction, said there would be no difficulty with regard to telegraph and telephone wires if if they were properly arranged; that he would not contemplate any fresh arrangement of those wires, but that he would contemplate a proper arrangement of the electrical conductors, and it would be quite unnecessary to disturb the telegraphs and telephones in any way whatever. Sir William Thomson said the same thing; he had no doubt that the difficulties could be got over by proper insulation, and that he did not anticipate there would be any trouble with the telephone companies from the carrying out of the London system. Referring to the question of short circuiting, and to the probabilities of a flare-up resulting from a break-down, he said a terrible story had been told by Mr. Crompton of the destruction of half-a-dozen cables and copper flying about in all directions, and that he had had the misfortune to be present when such accidents happened. That was the story of Mr. Crompton in brief, and was very high-flown in the matter of language and very solemn in the matter of tone; but on cross-examination he was bound to admit that it might have been the fault of the fuse, and that Mr. Ferranti would no doubt design a proper fuse. The learned counsel contended that with a proper fuse such results could not happen, as long before they could take place the fuse would be volatilised. Mr. Moulton had been absolutely silent in his summing-up, notwithstanding his elaborate cross-examination of Mr. Ferranti and his examination of Mr. Crompton upon this point, with the exception of what he would call, following Mr. Moulton's own metaphor, a little flare-up at the end which did not take five minutes. Referring to the question of the stoppage of supply from a break-down, the learned counsel referred to the evidence on the subject and as to the time occupied by the process of restitution he pointed out that Mr. Crompton put it at half a minute only and Mr. Swinburne a second or two. Therefore he thought they might resolve to ridicule all the silly talk about panics in theatres. He could understand a panic in a theatre arising from a tremendous blaze before people knew what they were about, even if the blaze suddenly ceased, because, of course, they might think a conflagration was about to set up, and they might make a rush; but he could not understand the common-sense even of the public of London being at such a low ebb that a momentary eclipse of light, a momentary darkness, lasting a second or two, would result in a catastrophe. According to Mr. Swinburne the thing would be over before they could scarcely recognise it; and before a lady had time to say "Oh dear," or a gentleman had time to say something else (laughter), the whole thing would be at an end. Another objection was that with regard to leakage from primary to secondary mains. That had been spoken of as though it was a recognised difficulty in working transformers, but that difficulty had been overcome long ago. The objection as to the dangers of transformers in private houses was answered by the appearance in the box of Mr. Heaphy, the adviser of the Phœnix Fire Office who was distinctly of opinion that there was no danger at all; and there was the further evidence of Mr. Ferranti, who said he used transformers in private houses for the last five years and never had an accident. The learned counsel proceeded to deal with other objections as to the want of uniformity of pressure with the transformer system and as to there being no known motor adaptable to the transformer system. On the question of the relative expensiveness of the transformer and the direct systems, he said he could not help thinking, in spite of what Mr. Moulton said, that the result of the comparison was just the other way about. They knew the end of their expenditure, but the advocates of the direct method supplemented by storage did not know the end of theirs. Dr. Hopkinson gave the cost of the accumulators at £30 per horse-power, with a loss of 30 per cent. in working. Mr. PEMBER then proceeded to deal with the position of the Chelsea Company and the Electrical Power Storage Company, maintaining that it did not warrant them in being entrusted with the Provisional Orders they sought. As to the position of other companies, such as the Westminster and St. James's Company, he said they were seeking to pick the plums out of the pudding, and that London ought to be lighted as a whole rather than small areas being allotted to small companies. Dealing with the dissents of the local authorities, he contended that they were not meant to be final, but that there were special circumstances connected with London which justified the Board of Trade overriding them if it thought fit. In somewhat strong terms the learned counsel dealt with the agreement between the Strand and Marylebone Board of Works and the Metropolitan Company, which, he contended, was contrary to public policy and contrary to the spirit of the Acts of 1886 and 1888, and virtually meant that the Metropolitan were willing to agree to anything in order to secure a monopoly. He did not think there was anything in the attitude of the local authorities which would prevent the Orders being given *sub modo*, leaving to the Board of Trade the subsequent decision of matters of detail.

Major MARINDIN said it would now be his duty to prepare his report to the Board of Trade, which he would do without loss of time, but he was sorry he could not give the parties any exact indication when it would be ready.

Mr. PEMBER expressed the thanks of himself and his colleagues to Major Marindin for the patient and able manner in which he had conducted the Inquiry; and Major MARINDIN having acknowledged the compliment, the Inquiry terminated.

CORRESPONDENCE.

THE GANZ ALTERNATING SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the reproduction in your esteemed journal of Prof. Forbes' Paper about electric lighting central stations, read before the Institution of Electrical Engineers, will you kindly allow us space to correct some erroneous remarks and statements upon our system of distribution?

Speaking of transformers, Prof. Forbes says:—"I have elsewhere described the Westinghouse converter, which I have tested and found to be very efficient, even though the largest one he is in the habit of supplying is only for forty lights. Only the larger size of Zipernowsky converters is so efficient. Three sizes are made, varying in efficiency from 95 down to 88 per cent., though the latter is a converter suitable for 25 lamps."

We cannot but remark that the manner in which Prof. Forbes speaks about the efficiency of the Westinghouse and the Zipernowsky transformer is apt to throw discredit upon the latter, which could not have been Prof. Forbes' intention, as otherwise he would not have failed to give exact numerical data about the Westinghouse converter also. Besides, the numbers given with regard to the Zipernowsky transformers are not right, as they differ from our measurements as well as from those of other electricians who have tested our transformers. The exact values of the efficiency are from 95·5 down to 92·5, the latter number relating to the smallest type of converter we manufacture for lighting purposes.

Though satisfied by the fact that Prof. Forbes recognises the lately patented Elwell-Parker dynamo as our oldest type with wooden cores in the armature coil, we cannot share Prof. Forbes' views in regard to the advantages of an internally rotating armature.

We cannot understand why the rotating magnet wheel may not just as easily be balanced as a rotating armature, especially as Prof. Forbes himself admits that the magnet wheels of our dynamos are very well equilibrated.

That, moreover, the armature winding of the Westinghouse dynamo might better withstand centrifugal forces than the

Digitized by Google

winding of the magnets of our dynamo, we must decidedly dispute. The single induction coils of the former dynamo are simply laid upon the bare drum, covered with mica, and then fastened by means of wires wound around them. The winding of our magnets is placed upon zinc shells, which are slid upon the magnet cores and held down by means of strong coil holders of bronze, which are again fixed by a bolt passing through the magnet poles.

Certainly this method of fixing the coils is a solid and constructive one. Besides, it is quite doubtless that a winding which has to produce high tension currents can be far better insulated when fixed that when revolving. A further advantage of our dynamo is that every single armature coil may be taken out and replaced by another one, whilst in the Westinghouse dynamo this is impossible. This advantage allows an easy and quick repair, and only requires a reserve of one or two coils for our dynamo instead of a whole drum for the Westinghouse dynamo.

It is, therefore, not at all in respect to firmness that we run our dynamo not at so high a speed as Westinghouse; only the relatively low number of alternations (5,000 per minute), which we have chosen on principle, has caused us to take a low number of revolutions, and not *vice versâ*, as Prof. Forbes assumes.

That we by this means are enabled to couple our dynamos in parallel is not a secondary result, but just the end we were aiming at; and we believe that at present no practical electrician will hesitate to acknowledge the coupling of the dynamos in parallel circuit to be a vital question of any parallel system of central station distribution.

The reasons which Prof. Forbes gives against the parallel coupling of dynamos do not exist, and even if they existed they could not be valid enough to render the parallel coupling of the alternating-current dynamos disadvantageous or even less desirable. A single district can as easily be cut out from a system of parallel-coupled dynamos as with independently running machines, seeing that the leads for each district can be branched off in the central station.

Prof. Forbes has seen an example of this in Rome, where six feeders are supplied from paralled-coupled dynamos. As to the increase of the resistance of the line with the use of alternating currents, it is only very small in our plants, because of the low number of alternations and the small cross-section. What is to be kept in mind is that the coupling in parallel of the dynamos is not identical with the use of one single main. If other manufacturers do not couple their dynamos parallel, it is likely that the reason is not that they have found this method of supply unsuitable, but lies elsewhere.

The introduction of great self-induction is not necessarily accompanied by a diminution of the plant efficiency, as the self-induction may be obtained, not only by the enlargement of the dimensions, but also by a change of the constructive forms.

To keep the tension of such a dynamo upon a constant value, the existing current must, indeed, be varied within further limits than in dynamos with smaller self-induction; but we think that the regulation in both these cases causes about the same difficulties; Prof. Forbes himself has acknowledged our method of regulation to be the best among all known to him.

As to the cost of transformers, they indeed rise with the use of a low number of alternations, but although the total cost of the transformers in a plant forms a considerable sum, the rise of this total sum is quite insignificant against the other advantages of a low number of alternations. In fact, the disadvantages in using a low number of alternations are disappearing against the advantages obtained thereby.

We are much astonished to see Prof. Forbes use the expression, "Gaulard and Gibbs system, with converter put in parallel," several times. We will only call attention to a Paper read by Prof. Forbes on February 19, 1886—that is almost a year after our first demonstrations in the Exhibition of Budapest—in which he declares the Gaulard and Gibbs' series system to be the only good one, and the parallel system to be quite impracticable. It was not until after we had already carried out several plants that Gaulard and Gibbs understood that the series-coupling renders the maintaining of a constant secondary tension impossible.

If the series system in 1885 was called the Gaulard and Gibbs' system, after those who first employed it on a larger scale, it is very unjust of an authority like Prof. Forbes, a few years later, after a better system had been found and employed by others (in this case indisputably by our engineers, Messrs. Zipernowsky, Déri and Bláthy) simply to ignore this fact, and even to christen the better system by the name of those who in the meantime have preferred to lay no further claim to the paternity of their own system. We are the more astonished at this proceeding of Prof. Forbes, as he brings in the above-mentioned wrong assertion in connection with the central station at Rome, and as he mentions immediately afterwards that he had received full information from the undersigned, while from our information, as well as from those of Mr. Pouchain and Prof. Mengarini, he quite certainly ought to have known that in Rome not the Gaulard and Gibbs, but the Zipernowsky-Déri-Bláthy system of distribution has been brought in use.—Yours, &c.,

GANZ AND CO.,
per C. Zipernowsky.

Budapest, April 30, 1889.

THE UNITED TELEPHONE COMPANY *v.* THE NEW TELEPHONE COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You are no doubt aware of the action that the United Telephone Company is taking with regard to all instruments that have been manufactured and sold by the New Telephone Company. I lately purchased some of these instruments, and am now required either to surrender them to the United Telephone Company or to pay a heavy yearly rental. If I give up these instruments I can get no compensation, for the New Telephone Company is now in liquidation. Had it not been so that company would no doubt have defended its customers from all claims. With the United Telephone Company might is evidently right, and finding a rival in want of funds, they take the opportunity of striking a blow which they know cannot be returned. There must be hundreds of purchasers of these instruments who are in the same position as myself, and who must be greatly inconvenienced by the high-handed action of the United Telephone Company. Might I suggest, through the medium of your paper, that though it may not be worth the while of any one single-handed to fight the matter, yet if a considerable number were to combine and refuse to give up the instruments they have bought and paid for, and also agree to share the legal expenses incurred, then such legal expenses would not fall heavily on any one. I consider we should have a very good case, and I would gladly subscribe my share and help to destroy a monopoly which greatly retards the use of the telephone amongst an enormous number of prople who would otherwise use it.—Yours, &c.,

J. A. McMULLEN.

25, Liverpool-street, London, E.C., April 7, 1888.

DR. LODGE'S EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The travelling brush noticed by your correspondent calling himself "Ignoramus" must, *I imagine*, have been merely an optical effect. I did not see it myself. May I ask if it was noticed by others?

I may take this opportunity of remarking that in the artistic improvements of my diagrams on your page 732, *case a* of Fig. 2 is omitted, and the sketch called "case *a*" is really a variety of *case b* (2).

My *case a* represented a simple flash from a single cloud to earth: the cloud not raining.

I fear the bottoms of the clouds are not flat enough to satisfy a meteorologist.

One or two other little errors:—In Fig. 1, case *b* (1), a dotted line from M to outside of jar is omitted. The last sentence of printing under the diagrams should run:—"In case *b* (1) the rain-shower or leak is permissible but unnecessary."—Yours, &c.,

OLIVER J. LODGE.

THE HÉROULT ALUMINIUM PROCESS IN GERMANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In No. 569, Vol. XXII., 12th April, of your esteemed journal we read on p. 644 a notice headed "Cowle Patents in Germany," the final of which runs thus:—"The Héroult process, which is employed at Oerlikon, is not, so we are informed, patented in Germany," which prompts us to submit the following corrections:

1. The Héroult process is not being practised at Oerlikon, but in our establishment at Neuhausen (Falls of the Rhine).

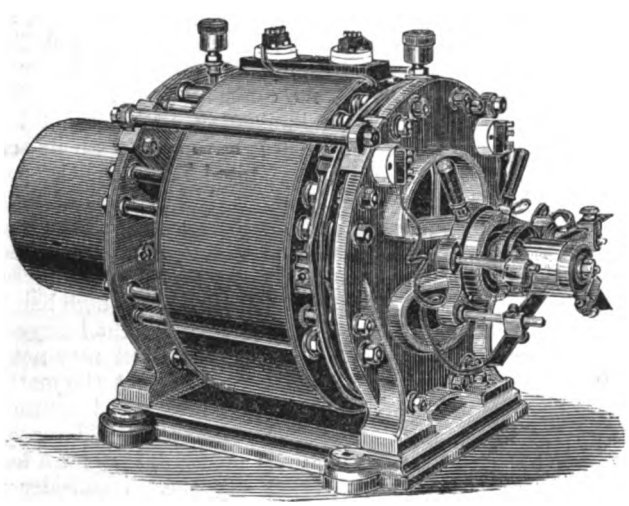
2. The Héroult apparatus for continual production of alloys of aluminium and similar metals by electrolysis is patented in Germany.

We request the favour of causing a correction of the said notice in the above sense to be inserted in your esteemed journal, and remain, Sir, yours, &c.,

J. CHINDLEY and W. WILLIAMS.
Aluminium-Industrie-Actien-Gesellschaft
Neuhausen, April 30, 1889. Der Vorstand.

THE GANZ ALTERNATING MOTOR.

The accompanying illustration is taken from a photograph of the new Ganz alternating motor, of which we gave some account



Ganz Alternate-Current Motor.

Owing to the indistinctness of the photograph from which the engraving is taken it is possible that the actual commutator may not be exactly as represented above.

in our issue of April 19. Messrs. Ganz and Co. inform us that they are already carrying out several installations for the transmission of power with the new motor. At a distance of 1½ miles from the Wiener-Neustadt Brewery water-power to the extent of 80 horse-power is available, and at this point a Ganz alternator, running at 500 revolutions, and giving 25 amperes at 200 volts, is now being erected for the supply both of light and motive-power to the premises. The lights are of course run off transformers. Power is furnished to the machinery by means of two alternating motors of 10 horse-power each and one of 5 horse-power. The two larger machines run at 830, and the smaller at 1,250 revolutions per minute.

Messrs. Ganz also send us the following table, in which some particulars as to the performance of the motor are given:—

Revolutions per minute.	Output alternate current motor.		Apparent energy consumed, Volt-Amperes.	Actual energy consumed.		Proportion between actual Watts consumed and apparent Volt-Amperes.	(Commercial) efficiency per cent.
	Horse-power.	Watts.		Watts.	Horse-power.		
600	15	11,000	18,000	15,800	21·5	0·88	77·0
700	19·8	14,600	24,200	18,600	25·2	0·77	78·5
730	30·7	22,400	29,800	27,700	37·6	0·92	80·9

COMPANIES' MEETINGS & REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The thirty-first ordinary general meeting of the shareholders in this Company was held on Wednesday, at Winchester House, Old Broad-street, under the presidency of Sir James Anderson (the Vice-Chairman of the Company).

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting and the minutes of the last ordinary and extraordinary general meetings. These minutes were confirmed as correct by the present meeting and signed by the Chairman. The report of the Directors was taken as read.

The CHAIRMAN expressed great regret at the absence, through illness, of Viscount Monck, and said he was quite sure the shareholders would join with the Directors in the sincere wish that his lordship's illness would be only of a temporary character. Fortunately there was little to say, for the report of the Directors was a very full and satisfactory one. It dealt with the accounts to December 31st last, and it would be seen that as compared with the corresponding period of the previous year there had been an increase of over £30,000 in the revenue, while the expenses had been more by £2,000 than in the preceding half-year. The increase in the expenses, however, had been mainly owing to the fact that they had written a certain amount off the value of the cable in stock—a plan followed by other similar companies, as cable was not now so expensive as formerly. In the working expenses in this country and at the stations there had been a saving of £400. In paragraph 4 of the report they referred to having reduced the tariff on the 1st ult.—too short a time, under any circumstances, to form any reliable idea as to the result of the alteration; but unfortunately there had been interruptions on the Western and Brazilian Company's system and the Government land lines, so that they had had a very bad month. They had a right to expect that they might hear any day or hour of the restoration of the whole of the system, when he hoped that their traffic would come back. It was right for him to have mentioned this accident, which occurred last month, though the report only went up to December 31. In paragraph 5 reference was made to the African Direct Company, in which they had £75,000 invested. The Eastern and South African Company had extended that line down to the Cape of Good Hope, and they had made a joint-purse arrangement with that Company and the African Direct Company, and all the connecting companies. That line would be open for traffic within the next forty-eight hours, and he thought that the £75,000 referred to, which was now lying unproductive, would then produce something. He concluded by moving the adoption of the report and accounts.

Mr. FREDERICK YOULE seconded the motion.

Mr. NEWMAN inquired why the Directors had reduced the tariffs if they anticipated a loss. This line was mainly a business line, and people who had to deal with thousands and tens of thousands of pounds were not likely to be stopped from telegraphing for the sake of a few shillings.

Mr. W. GRIFFITH thought the shareholders might congratulate themselves on the state of the Company's business up to December last. They must also join in the regret which had been expressed at the absence of Viscount Monck, but they might congratulate themselves on the able way in which his lordship's place at that meeting had been filled. The Directors proposed in June to distribute £13,000 out of the amount now carried to next account, or 1 per cent. on their share capital of £1,300,000; and if they could distribute the unclaimed dividends and interest, amounting to between £6,000 and £7,000, they could divide something like 10s. per cent. more. He might state that within the last six months certain changes had been made in the law by which the accounts of companies could be simplified, and by which trustees, directors, and others might get rid of such items as he had mentioned after a certain period without any danger to the Company and with great benefit to the shareholders.

The CHAIRMAN observed that the unclaimed dividends had now been greatly reduced.

The MANAGING DIRECTOR: The amount stands to-day at £1,000 or thereabouts.

The CHAIRMAN, continuing, said they must not be in a hurry to deal with this item. With regard to the remarks of Mr. Newman, he thought that all who were closely watching the interests of telegraph companies had come to the conclusion that low tariffs would be forced on them if they had not the good sense when they could afford it to reduce the rates gradually. It was quite true that a man who spent 6s. a word would spend 7s., but it was also true that if the tariffs were reduced an impulse would be given to the traffic, which might otherwise be stagnant. He thought, too, they must admit that 7s. was a high tariff for a single word; and now that they had had it for many years, and had paid good dividends, and had duplicated their cable, it was only wise to reduce the rate, and to look to the

Digitized by Google

development of the traffic to recoup them for the sacrifice which they would make at first.

Mr. NEWMAN said it was not only in their Company but in others that the mistake was made of considering the public first and the shareholders afterwards.

The CHAIRMAN replied that the shareholders must allow the Directors to judge of the expediency of what they did. They knew the demands which were made upon them in every direction, and the threats that were made about competition, and those threats would be carried out, and very properly carried out, if the rates were not reduced.

The resolution was then carried unanimously.

Mr. JOHN ANDERSON proposed a vote of thanks to the Chairman and Directors, which was seconded by Mr. GEORGE ANDREWS.

Mr. GRIFFITH, in supporting the motion, said that their business was increasing, and if the Directors thought it wise to lower the rates the shareholders must admit that they had greater experience as to the way the business of the Company should be managed. He agreed that it was unpleasant to see the rates lowered, and they all desired an increased dividend ; but, on the other hand, if the business increased they would not lose by the lowering of the rates, and they would certainly save themselves from the serious danger of opposition from which the Anglo-American Company, for instance, had suffered so greatly. He thought the shareholders might leave the question of the rates in the hands of the Directors.

The resolution was carried unanimously.

The CHAIRMAN, in acknowledging the vote, observed that the question of reducing the tariffs had been before the Directors for years, and he was sure that in the course they had taken they had gone in the right direction.

The proceedings then terminated.

West India and Panama Telegraph Company.

The twenty-fourth ordinary general meeting of the members of the West India and Panama Telegraph Company (Limited) was held at Winchester House, 50, Old Broad-street, on Wednesday, the 8th May, 1889, under the presidency of Mr. C. W. Earle.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the minutes of the last meeting, which were confirmed by the present meeting as correct. The report of the Directors was taken as read.

The CHAIRMAN : When I had the pleasure of meeting the shareholders this time last year, I called their attention to the fact that the half-year's accounts which they were at that time considering were the best they had had presented to them since the autumn of 1883. On this occasion we have an improvement upon the corresponding period of 1887 of about £1,600, although in the half-year of 1887 we had some advantages which we have not had in the past half-year, in the hire of the ship and the employment of it, thereby relieving our accounts of so much during the time that one of the ships was coming home to take out new cable to the West Indies. This improvement of £1,600 is partly accounted for by the increase of the traffic of about £1,050 ; but we must look for something to set off against the extraordinary advantages of the preceding period, and these must be found under Abstract C, which deals with the repairs of the cables. We have there an expenditure of £8,402, against an expenditure of some £12,000 odd in the corresponding period of the previous year, and this is the main cause of the improvement in the half-year under review. I may tell you that, taking the average for the last nine half-years, the expenditure under Abstract C, which refers to the repairs and renewal of cables, has been about £5,000 more than it was this half-year, and, therefore, in that respect the half-year has been an exceptional one. I wish particularly to call the attention of the meeting to the fact, because sometimes we find that when there is a good half-year like this it is made use of to advocate various schemes of dividing the reserve ; and, in fact, at such times people are led to suppose that all our difficulties and dangers are passed, and that we are going to enter into a time of great prosperity ; but every one who has anything to do with telegraph cables knows that the accidents to which they are liable are very uncertain in their coming, and although we have done very well this half-year with our cables, that good luck may not follow us in the future. I am rather of opinion that owing to the experience we have gained of the nature of the seas in which our cables lie, we are able to do something to diminish the interruptions, but that may be mere supposition. It is very difficult to prove—it requires a very long time and long-continued experience to prove—the success of such an occult business as the keeping of cables in repair. With respect to our traffics for the last five half-years, we have had a small increase, and in most businesses that would lead some one to suppose that there was some development going on in the traffic of the West Indies ; but when you look back at the traffic returns of a longer period than five half-years you see what falls and bounds to which our traffic returns are exposed. In the last half of 1885 and the first half of 1886 we had a falling off amounting to £7,000 over the preceding period. Now we have nearly recovered that by the gradual increase in five half-years, and we are about at the same level as we were then. Therefore, I am not disposed to be too sanguine about any great development and increase of traffic to the West Indies. It is a traffic that is liable, like our repairs, to great fluctuations, depending, as it does, principally upon the conditions of trade and the condition of the sugar industry, which are so exposed to influences of various kinds. There is an allusion in the report to the French Company that has been started in our very midst. At present that Company does not interfere with us very much. It goes to Venezuela, a point we do not touch at ; and though it has taken some little traffic away that used to come from Venezuela by post to our line, yet I do not think there is very much harm done at present. The danger, of course, of such an organisation is the temptation to go to other places which are served by us ; and when you consider the very small amount of traffic that there is at almost every one of the stations (at none is there a traffic of any considerable amount), it is rather curious that people should wish to lay other cables for carrying what traffic there is. But our friends the French are a curious people, and if they get an idea that the glory of their country is concerned, or that perhaps a little blow can be given to England or English interests they come down with their 5-franc pieces with great alacrity. Therefore it is a source of some anxiety that this French cable goes through the Caribbean Sea. With respect to our prospects, it is not safe at any time to prophesy, but I think this half-year that we are now in—the first half of 1889—will see us through the arrears on our First Preference Shares to a certainty. We shall then commence to pay off the arrears on the Second Preference Shares, and if all goes well—if the traffics remain as now, and no great misfortune occurs to us—I think in the course of two years we shall be quite free from all these liabilities, and we shall begin to pay something to our ordinary shareholders, who deserve every consideration after the long and patient way in which they have borne the privation of all dividend. With these remarks I beg to move :

"That the Directors' report and accounts to the 31st December, 1888, submitted to this meeting, be read, and the same are hereby received and adopted, and that, as recommended by the Board, a payment of 12s. per share on account of arrears of dividend on the First Preference shares be and the same is hereby declared."

Mr. WILLIAM FORD : I beg to second the resolution, and I have the very greatest pleasure in doing so, because I really believe that the accounts indicate a greatly improved prospect for the ordinary shareholders.

Mr. FITZGERALD said he desired to ask one or two questions respecting matters of policy, for other questions were replied to with the greatest readiness at the office. He observed that in the past half-year £1,000 had been put to the reserve fund. In the previous half-year the amount was £2,000, and in the half-year before that £3,000 was put to that fund, so there had been a gradual reduction. At the present time the reserve fund amounted to £134,000 odd, plus what the securities would fetch in the market by their increased value over cost price. Roughly, he believed their securities were worth within £2,000 of £150,000. Besides the £1,000 which he had mentioned as having been added to the reserve fund in the past half-year, the interest on the fund had also been added to it. The interest on the reserve fund amounted to £5,000 a-year, so that in the past half-year the reserve fund had been increased by £3,500. The question he desired to ask was whether, having regard to the long time during which the shareholders had not received any dividend, they might take it that unless any unforeseen circumstance arose in the future that amount of £3,500 would be something like the amount that would be put to the reserve fund in future half-years, so that the day in that case would not be far distant when the interest of the reserve fund would be considered by the Board as sufficient by which to increase that fund. In that case he thought the Chairman's figures were not quite sanguine enough, because he himself thought that within 18 months or two years the whole of the present liabilities would be cleared off, even supposing that the present traffic did not increase, and that they could not effect any other economies. In that way about £17,000 would be available for the Ordinary dividend, which would give something like 2 per cent. on those shares, and at their present miserable and, as he considered, wrong price on the market, the return would be about 10 per cent. He wished it to be clearly understood that he made these observations without any hostile feeling to the Directors. He also desired to know whether it was not possible to do the repairing work with one vessel instead of two. He found that in the previous half-year one of the vessels was employed under charter party. He thought it reflected great credit on the Directors in having obtained employment in that manner for one of the vessels. But naturally the question arose whether it was possible to do with one vessel, which would mean a very considerable saving each half-year.

Sir G. H. CHAMBERS wished to echo the remarks made by the previous speaker as to the inadvisability of anything in the way of hostile criticism. No one knew better than he himself that when the responsibilities of directors were placed upon gentlemen they ought to receive all the support that could be given to them by their shareholders. At the same time, when there were differences of opinion he thought it was just as well that the shareholders should state their views, which should have the consideration of the directors. The amount payable to the Preference shareholders annually was £23,540. The accounts now before them and the accounts of the previous half-year showed that out of the profits of the year 1888 they had paid no less than £41,475, that being a difference of £17,935 taken out of the profits of 1888 towards paying the arrears on the Preference shares. The accounts also showed the amount now due as at the 31st December, after the present payment had been made, and that amount would be about £35,000 ; therefore in the course of a couple of years, as stated by the Chairman, they might expect that that amount would be disposed of. They would then have for the ordinary shareholders nearly £18,000 available for dividend in the year 1891. The accounts showed, moreover, that in the course of the year 1888 they had added £7,820 to the reserve fund, partly from the dividends received on the investments of the fund. Adding that sum to the amount of nearly £18,000, which they would not have to pay in 1891 to the preference shareholders, it would be seen that if the two amounts were put together there would be a fund available for dividend on the ordinary shares enough to pay 3 per cent. He did not want to anticipate too much, but it was quite clear that the Chairman was looking forward to the payment of an ordinary dividend at the date he (the speaker) had mentioned. But the question was whether they might not receive something in the meantime. It was clear that of the ordinary revenue of the company the ordinary shareholders had no right to any portion until the preference

Digitized by Google

shareholders had received their rights. Their position was about £14,000 better than appeared from the accounts before them—that was in the increased value of their investments; and so far as one could judge, knowing how much the value of money had been diminished, they might at least expect that the present value of their investments would be maintained. It must be remembered that that fund had been contributed out of money which would have otherwise been divisible among the ordinary shareholders. The fund was for the protection of the debenture holders in the first instance, then of the preference shareholders, and the ordinary shareholders followed. He thought under these circumstances the increased value of the securities might be regarded as a fund which really belonged not to the Preference shareholders but to the ordinary shareholders of the Company. They had paid out of revenue over £23,000 a year for repairs and renewals, and that had been extending over a considerable period. At the present time a large part of their system was new cable, and it was estimated that the life of a cable was thirty years. Assuming that that was so, and that they continued to pay out of revenue for thirty years so much as had been charged in the accounts there would be a sum of £700,000 for repairs and renewals without touching the reserve fund. It appeared to him that the amount of the reserve fund was now sufficient for all ordinary purposes unless anything extremely adverse occurred. Then there was the amount of the profit on the investments, and the interest on the investments; it would be a question whether that might not be appropriated to some dividend for the ordinary shareholders, without waiting for the year 1891 to come. He thought the ordinary shareholders were quite entitled to the improved value of the property; and it would be the duty of the Directors to take that point into their consideration, and to decide whether some dividend might not be paid to the ordinary shareholders, as he (the speaker) had suggested. It would be an advantage to the Company to be declaring a dividend.

Mr. GUESDON said that all the shareholders appeared to be of one mind as to the confidence they reposed in the ability of the Board. He was not himself quite so much of a pessimist as the Chairman with respect to the future of the West Indies. He thought that circumstances were occurring, particularly the better position in which sugar would be placed, which he hoped would increase their traffic receipts. With regard to the question which had been raised as to the French Company and the possibility of competition, he held it to be a matter of the highest importance that they should have a strong reserve fund, because when one was able to show to an opposition company that one had the tools to fight with it made a very great impression, which would make their possible intended opponents thoughtful before entering into a fight. He thought it was of great importance that the reserve fund should be left, as hitherto, entirely at the discretion of the Directors. The experience which the Board had gained as to the management of the Company's affairs must render them capable of forming a sound opinion, and he was sure they would be quite as pleased to pay a dividend as the shareholders would be to receive it. Business, however, was one thing, and sentiment another, and he hoped that nothing would be allowed to interfere with what business experience and sound policy would dictate. He hoped, therefore, that the shareholders would still exercise patience and leave the Board to pay a dividend when they could do so.

Mr. RUSSELL referred to the £50,000 of Debentures bearing 5 per cent. instead of 6 per cent. as formally. He congratulated the Directors on the reserve fund, and as to the discretion they had shown in investing the money forming it, the existence of which greatly strengthened the position of the Company. Did he understand that the reserve fund was hypothecated with all the other assets of the Company to the debenture holders? If that were so the reserve fund would have to be reduced by something like £50,000. They had to pay £2,500 a year for interest on the Debentures, and he thought it would have been much wiser from a financial point of view if the Directors had sold out some of the stocks at a considerable premium, and so have obtained the money which they required when they issued the Debentures. They would thus, he said, have saved £900 a-year. He wished to know the opinion of the Directors as to the life history of a cable. He believed that in their case twenty-five years would be an under estimate. He thought they might do with one ship if they put down good cable. It was an immense expense to have two ships. The Company was now earning a dividend on the Ordinary shares. He congratulated the holders of the First and Second Preference shares, as they were called—when in reality they were guaranteed shares—for the dividend on them was not contingent on the profits of each separate year. He thought if they had been, all the shareholders in the Company would have been much better off.

Mr. SAUNDERS inquired whether the investments were shown at their cost price, or were set out at their market value?

The CHAIRMAN: Their cost price.

Mr. GUESDON inquired when the Debentures matured?

The CHAIRMAN: At the end of 1891. Considering the tone which has characterised them it is a great pleasure to me to answer the criticisms which have fallen from the different shareholders. Mr. Guesdon referred to my knowledge of the prospects of the West Indies sugar industry. I cannot accept that compliment, especially in the presence of my friend, Sir George Chambers, who is very much concerned in the West Indies, and in the sugar and other industries there. I think I had better first deal with the question concerning the ships. For a long time in this Company we had only one ship, and it was with considerable heart-tearings, if I may use that expression, that we at last decided that we must have two. In looking back at the last two half-years, it is possible to say that we should have done as well with only one ship; but you must remember that these accidents that happen to cables are cumulative. They occur in groups, and we are then at our wits' end to know how to repair them. It is not only the loss of traffic that we have to consider but the injury it does to us in connection with the Colonies.

A SHAREHOLDER inquired whether the cables were not duplicated.

The CHAIRMAN: Some of them. We have two cables that are not, the one to Demarara and the other to Barbadoes. The Colon cable is not duplicated, but that is not important. Sometimes we have two cables break at the same time. Some of these small cables go in pairs, and when such breaks occur the Colonies are without communication, and there is a considerable howl. We have had as many as 11 cables broken at one time.

Mr. FORD: The loss of revenue consequent on that interruption was greater than the cost of the ships.

A SHAREHOLDER: When was that?

Mr. FORD: In 1880.

Mr. FITZGERALD: We have better cables now.

The CHAIRMAN: I cannot say that. The original cable was quite good enough. It is picked up now in first-rate order where it lies on good ground, but no one would like better than the Directors to get rid of one of these ships. It is a very heavy incubus, but the second ship was not bought hastily. Though you may go on for a little time without the ships being much used, yet when the breaks occur you would be in a very bad way if we had not these vessels, and we should have a great loss, not only of the traffic, but the subsidies, and there would also be the loss of the good feeling in the Colony, which is rather difficult to obtain. I do not see my way yet to hold out any hope of getting rid of the second ship.

Mr. FITZGERALD: The matter will not be lost sight of?

The CHAIRMAN: No; but we have a great many complicated questions to consider with respect to that.

Sir JAMES ANDERSON: We have often discussed it.

The CHAIRMAN: With regard to the question of reserve fund, let me say that the additions to it are not made by rule of thumb. It is done on a certain calculated system. For many years our reserve fund was very much in arrear of what it ought to be to pay for the depreciation calculated up to that time for the life of our cables, and we had therefore to add very large sums to bring up the amount to the prescribed level. The fund is now about at the level. We have had nineteen years' life

of the cables, and our calculation brings us up to requiring that sum that is now in our books as reserve fund. The depreciation that ought to be laid aside is laid aside up to the 19th year of the Company's cables. When we put in any new cable we take the value of it into consideration in setting aside a sum to reserve—that is, if we put a new bit of cable into an old cable that has been 10 years in existence we take into consideration the 10 years' accumulation. The whole thing is calculated on a system taking into consideration three things—the life of a cable, the interest we can get on prudent investments, and the cost of a cable. The reserve fund is a depreciation fund which ought in the time that we allow for the life of a cable to put us in a position to renew the whole cable. That is to say, we ought after 30 years, either in meal or malt, either in new cable put in or in sovereigns invested, to have money enough to cover the whole cost of the system. Whether we shall go as far as that I cannot say. It is a good big sum, but you must think of what the reserve fund may be called upon to supply. There are some Directors here who will tell you of the repair of a cable that cost £90,000. One cable in this Company cost us first and last to repair £50,000—the cable between Jamaica and Porto Rico. In cable alone that cost £32,000, besides the expenses of the ships. It does not therefore do to be too hopeful as to being able to take money out of the reserve fund and pay it away in dividend. The profit that has been made upon the investment has been very fair, amounting to about £13,000, but whether the directors would consider it prudent to deal with that in the shape of dividend I have not had an opportunity of discussing with them. You must remember that the market might fall, and in that case, instead of finding ourselves several thousand pounds to the good we should be several thousands to the bad.

A SHAREHOLDER: In case of war?

The CHAIRMAN: Yes, in case of war. The renewal of the debentures occurred two years ago. We renewed them at 5 per cent. instead of 6 per cent. Our having those £50,000 of debentures has proved more valuable than if we had sold any of our securities, owing to the increment in their value. Had we paid off that £50,000 we should not be as well off as we are. We cannot pay them off now until the period of five years has elapsed.

Mr. JOHN NEWTON: Instead of paying off the debentures you have kept your securities, which have since increased in value by £12,000, and for that you have paid £500 a-year. I think you have in that way made a good bargain.

The CHAIRMAN: We shall consider all that has been said. He then put the resolution, and it was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. FORD, Mr. Henry Holmes was re-elected a Director; as was also Mr. Henry Weaver, on the motion of the CHAIRMAN, seconded by Sir JAMES ANDERSON.

Mr. J. G. Griffiths was then re-appointed auditor.

Mr. GUESDON then proposed a vote of thanks to the Chairman and Directors.

Mr. FITZGERALD seconded the motion, which was carried unanimously.

The CHAIRMAN briefly acknowledged the vote, observing that it was one of the bright moments in a somewhat anxious business to receive such a cordial acknowledgment from the shareholders of their appreciation of the services of the Directors.

The proceedings then terminated.

NEW COMPANIES REGISTERED.

THE ELECTRIC TRAMCAR SYNDICATE (LIMITED).—Registered by Davidson and Morris, 40 and 42, Queen Victoria-street, E.C., with a capital of £20,000 in £10 shares. Object, to acquire the letters patent granted to A. J. Jarman for an invention for "improvements in the construction of electro-motors for the propulsion of tramcars, electric locomotives, vehicles, and other purposes." The number of directors shall not be less than three nor more than seven. The first are J. Muirhead, P. E. Lentilhac, and H. G. Hemmerde. H. J. Archer, if willing to act, shall be appointed after completion of purchase. Qualification, £500 stock. Remuneration to be determined in general meeting.

THE JENSEN ELECTRIC MANUFACTURING COMPANY (LIMITED).—Registered by Batten, Proffitt and Scott, 32, Great George-street, S.W., with a capital of £80,000 in £5 shares. Object, to carry out an agreement, dated April 26, made between Clifton Shield and C. F. Helder of the one part, and J. M. M'Donnell, as trustee on behalf of the company, of the other part.

KESWICK ELECTRIC LIGHT COMPANY (LIMITED).—This company was registered on the 1st inst., with a capital of £5,000, in £1 shares, to provide Keswick and its neighbourhood with the electric light. Registered without special Articles.

LOTHAMMER GAS MANUFACTURING COMPANY (LIMITED).—On the 29th ult. this company was registered with a capital of £60,000, in £1 shares, to acquire certain patent rights in relation to improved portable apparatus for the manufacture of gas, upon terms of an agreement between François Josué Lothammer and S. H. Blumfield, and to manufacture gas and electrical apparatus generally. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first; remuneration, £100 per annum each, and in addition 5 per cent. on the net surplus profits, after payment of 10 per cent. per annum dividend, but the total remuneration is not to exceed £2,500 per annum. Registered office, 6, Lombard-court, E.C.

PONTYPRIDD ELECTRIC LIGHTING COMPANY (LIMITED).—This company was registered on the 30th ult., with a capital of £10,000 in £5 shares, to supply electricity for light and power to the parishes of Pontypridd and Ystradyfodwg, county of Glamorgan.

CITY NOTES, &c.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION.—The debentures of the Anglo-American Brush Electric Light Corporation were over-applied for, and the letters of allotment and regret have been posted.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended April 26, 1889, amounted to £3,200.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of April were £4,000, as compared with £3,705 in the corresponding month of last year. The receipts for the month of January, estimated at £3,100, realised £3,221.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of April, 1889, amounted to £1,867, as compared with £1,800 last year.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this Com pany for the month of April, 1889, amounted to £51,452, and to £51,582 in the corresponding period of 1888.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of April were £42,709, as against £37,331 for the same period of 1888.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of April, 1889, amounted to £21,000. From the 1st January to 30th April, 1889, they were £84,000, against, in the corresponding months of 1888 and 1887, £85,200 and £81,520 respectively.

MEXICAN TELEGRAPH (CABLE) COMPANY.—We gave the approximate result of last year's working in our issue of Feb. 22, p. 467. Later advices report that a dividend of 2½ per cent. has been declared upon the capital of $1,500,000. The earnings for the first quarter of this year are returned as follow (three months to March 31):—

	1889.	1888.	Increase.
Earnings	$94,271	$84,946	$9,325
Expenses	16,000	14,695	1,305
Net	$78,271	$70,251	$8,020

It will be seen that the net profits have increased over 10 per cent.

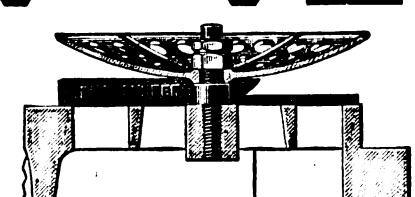
WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month ended 30th April, 1889, amounted to £8,125.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended April 26, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £2,009.

CHANGE OF ADDRESS.—The Monte Video Telephone Company (Limited) notify their removal to 25, Abchurch-lane, E.C.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 574.—Vol. XXIII. FRIDAY, MAY 17, 1889. Price Sixpence.

NOTES.

We have much pleasure in being able this week to fulfil the promise held out in our recent obituary notice of the late lamented Secretary of the Postal Telegraph Department. A finely-executed steel plate portrait of Mr. Patey is published with this week's issue of *The Electrician*, and we feel sure that the picture will be recognised as a most excellent likeness, and a work of art not unworthy of its subject.

We have received the following communication from the Secretary of the Institution of Electrical Engineers:—

"Dear Sir,—I am instructed to inform you that the Council have made arrangements for your being furnished with an abstract of the discussions at our general meetings. . . . Although the arrangement has only been made for the present year, the Council hope to be able to continue it in the future.

"Yours faithfully,

"(Signed) F. H. Webb, Secretary.

At the meeting of the Institute on Thursday next Mr. Mordey will read a Paper "On Alternate Current Working," on which occasion the President (Sir William Thomson) will occupy the chair. We believe that Mr. Mordey's Paper will prove to be of the highest interest; experimental results of a novel character may be looked for, and an attempt will be made to arrive at definite conclusions on several outstanding questions. This should, according to the programme, be the concluding meeting for the present Session; but in order to allow the Paper to be discussed it is understood that an extra meeting will be arranged.

The first evening of the discussion on Dr. Lodge's Paper at the Institution of Electrical Engineers was chiefly remarkable for the quantity of good-humoured *badinage* which was evoked, though candour compels us to own that the witticisms were not invariably of the most startling brilliancy. This result is not altogether what had been expected of the occasion, and, in fact, we could well have spared a good deal of incidental verbiage if we might thereby have gained a more serious consideration for the scientific aspect of the questions supposed to be under discussion. Mr. Preece, who spoke at great length, certainly did score a point when he observed that it remained with Dr. Lodge to show that the phenomenon of discharge from a metallic plate was strictly comparable to that of a thunder-cloud. His speech—which, as we have already observed, was rather long—was, however, chiefly devoted to the endeavour to show that the effects recorded in particular cases of lightning flashes could only have been caused by a uni-directional current. But in answer to this it is sufficient to observe that even an oscillatory discharge results in the final transfer of a definite quantity of electricity in a definite direction; and this, together with the observation of Prof. Ewing (*Electrician*, October 5th, 1888, p. 712) as to the effect of the diminishing amplitude of the oscillations, seems sufficient to account for all the known facts. On the other hand, Mr. Preece (whose remarks, we may add, were by no means brief) made not the slightest attempt to explain the various phenomena of surging, side-spitting, and other well-established inductive effects, which form so important a feature of Dr. Lodge's argument. Nevertheless, so confident is he in his opinion that lightning is a non-oscillatory discharge that, for the advancement of science and the honour of the Lightning Rod Conference, Mr. Preece is fully prepared to sit upon a barrel of gunpowder if protected by a conductor whenever a thunder-storm next arises. Prof. Adams, as Chairman of the Conference felt equally bound to maintain the infallibility of the opinions arrived at in 1881, and to do his best to slur over the value of the evidence since brought into court. Prof. Fitzgerald's speech made one regret that we cannot oftener have the pleasure of hearing him in London. He was unable to see that anything that had been said tended to upset the theoretical conclusion as to the usually oscillatory character of the discharge; but he agreed with Mr. Preece that it was desirable to repeat the experiments with a charged body more nearly resembling a storm-cloud. By the bye, we must not forget to mention that on this occasion Mr. Preece spoke rather longer than anyone else.

The statement that Electricity had annexed the whole domain of Optical science is fast being proved to be no empty boast. Already Dr. Hertz has made us familiar with the phenomena of reflection and interference of ether waves due to electro-magnetic radiation (*i.e.*, "light" waves whose length is enormous in comparison with those of the visible spectrum), and by means of a prism of pitch, with sides a metre square (see *The Electrician*, Nov. 9, 1888, p. 16), he has obtained an experimental proof of their obedience to the laws of refraction. Now, however, Dr. Lodge has gone a step further, and at the Physical Society, on Saturday last, he detailed a series of experiments carried out

Digitized by Google

with a pair of plano-convex hemi-cylindrical hyperbolic lenses, also made of pitch. Each of these lenses weighs 2 cwt. and stands 85cms. high. The cylindrical shape was of course selected in order that the "oscillator" and the "resonator" might be placed wholly in the focus of the lens. With this apparatus he has performed such experiments as would be made with a beam of light and similar lenses of glass. Prof. FITZGERALD is anxious to go further still, and he is now endeavouring to obtain evidence of phenomena cognate to diffraction and to Newton's rings. As to the actual or possible existence of such phenomena —whether they be discoverable or not—it is scarcely possible to doubt.

IT is somewhat unfortunate that these experiments, which would otherwise be within the reach of everyone who possessed an influence machine, and who has mastered the general principles of electric radiation, can only be performed with lenses and mirrors, whether of glass or of pitch, of somewhat large and unwieldy dimensions. One reason for this is referred to in Dr. LODGE's Paper; but in the case of mirrors Prof. FITZGERALD mentioned after the meeting that this difficulty was first pointed out to him in a private letter from Dr. HERTZ, who stated that he had found that the oscillator tended to set up electrical vibrations in the metal of the mirror itself. This causes a concentration of electricity at opposite points near the edge if the mirror extends only to the limits of sensitiveness, but the effect is greatly diminished by increasing the size of the mirror.

ELECTRICAL engineers as a body have long since arrived at the conclusion that the dynamo has nothing to fear from the competition of the zinc battery. In face of the long experience of the past, it demands some hardihood even to hint at the possibility of the ultimate salvation of the primary battery as a source of electrical energy on the larger scale. Waste products—once the hope of every sanguine soul—are long since proved to be a delusion and a snare. Suppose, however, it were possible to work your primary battery upon an entirely regenerative principle; that is to say, to recover the zinc as metal, and the solution in its original form, then it follows that, except for inevitable wear and tear, cost of material would be a first charge only. This would be a most important step gained. We should have next to consider what is the cost of effecting the re-conversion. If this be accomplished—that is, *wholly* accomplished—by electric energy, we fall back upon the principle of the secondary battery, and we have merely to inquire what is the efficiency of the battery when used as an accumulator. There is, however, this difference: in the case of the zinc battery the metal passes into solution, and is not transferred to the negative plate. Consequently the re-conversion cannot be effected within the cell. This imposes the necessity of taking the battery to pieces; but, on the other hand, it has the advantage of allowing a large quantity of material brought from different batteries to be treated at one operation. We can now present the enquiry whether a zinc cell, such as we have hinted at, could compete with the dynamo in the wholesale distribution of electricity in the following form:—(1) What is the efficiency of the cell (regarded as an accumulator) compared with the efficiency of the distributing and transforming plant of the central station? (2) What would be the first cost of the batteries for a given district as compared with the first cost of distributing and transforming plant? (3) What is the cost of working and maintenance (including interest and depreciation) in each case, taking into consideration the cost of manipulation of the cells? We hope shortly to show that some advance has actually been made in the direction indicated, though we may leave our readers to reply to the above questions to their own satisfaction. We think, however, after what has been said, it will at least be admitted that the problem is worthy of candid and respectful consideration.

AT the meeting of the Committee of the Electrical Trades Section of the London Chamber of Commerce, on Monday last, the most important business in hand was the reception of the report of the Committee on Railway Rates. The text of this very able report will be found in this issue, and we have also dealt with the matter at some length in another column. We need, therefore, only remark here that the subject is one of great importance to the electrical trades, and that the report and schedules should receive the careful attention of everyone interested. A report was also received from the Correspondent (Mr. A. P. TROTTER) on the work already done by the Sectional Committees. From this report it appears that committees have been appointed to report to the General Committee on the following questions:—Overhead Wires, Railway Rates, the Establishment of a Standardising Laboratory, Standard Types of Apparatus, Standard Specifications. The three first-named Committees have already done good work. The Committee on Overhead Wires has induced the Board of Trade to promise that a copy of the proposed regulations shall be forwarded for its observations before their final issue. (We may add that at the present moment these regulations are in the hands of the Solicitor to the Post Office.) We have already referred to the work of the Railway Rates Committee. The Committee appointed to consider the question of providing a standardising laboratory forms part of a joint-committee in connection with one appointed by the Council of the Institution of Electrical Engineers, with whom the Board of Trade are in communication, and who have already held several important meetings. The two last-named Committees can hardly be said to have got to work as yet, although Mr. TROTTER is now engaged in collecting information to lay before them. We think it will be admitted that this is not a bad record—especially when it is remembered that we are now passing through a period of the greatest activity which the industry has yet experienced, and that the men from whom such Committees are formed are not, as a rule, amongst the least busy.

THE great importance of the question of providing a properly equipped Standardising Laboratory is perhaps scarcely fully realised as yet by the industry at large. It is, however, not too much to say that in the absence of such provision the Electric Lighting Acts will be simply unworkable. In support of this assertion we need only quote two or three of the clauses

Digitized by Google

which are common to all Licenses and Orders. Take, for instance, the following clauses:—

"The local authority shall keep all instruments used by them for the purposes of testing any supply of electricity by the Undertakers in efficient working order, and any electric inspector appointed under this Order may, from time to time, examine and record the readings of such instruments at such times and in such manner as he may be directed by the authority by whom he is appointed, and any readings so recorded shall be receivable in evidence." . . . .

"If any difference arises between any consumer and the Undertakers as to whether any meter whereby the value of any supply of electricity to such consumer by the Undertakers is ascertained (whether belonging to such consumer or the Undertakers) is or is not in proper order for correctly registering such value, or as to whether such value has been correctly registered in any case by any meter, such difference shall be determined upon the application of either party by an electric inspector, or where the local authority are the consumers by an inspector to be appointed by the Board of Trade, who shall also order by which of the parties the cost of the proceedings before him should be paid. Subject as aforesaid, the register of the meter shall be conclusive evidence in the absence of fraud of the value of any supply of electricity by the Undertakers to any consumers."

The question immediately arises, *Quis custodiet ipsos custodies?* Who shall standardise the Inspector's standards?

THE Committee of the Electrical Engineers which is dealing with this question is now engaged in drawing up a report showing what has been already done in Berlin, Munich, Hanover, Paris and elsewhere. This report, which will also contain plans and estimates, will be presented to the Board of Trade, and at the same time a deputation will wait on Lord SALISBURY to endeavour to secure his interest in the undertaking. It is, however, evident that no scheme can be considered satisfactory unless the Government are prepared to find adequate funds for the necessary equipment. Building operations will have to be undertaken, and the instruments to be provided must possess every known refinement tending to ensure accuracy, and this cannot be done without money—£10,000 or £12,000 at least will be wanted. There is, however, every reason to believe that in a short time the establishment will become self-supporting. So fully is this belief entertained that an offer was recently made by a private individual to build and equip a standarising laboratory merely as a commercial speculation if the Board of Trade would agree to recognise its work as official. This offer was, however, declined.

AN additional estimate has been issued, showing the amount which will be required during the year ending March 31, 1890, to defray the expenses connected with the acquisition of the Submarine Telegraph Company's property, required for the Post Office service. The total amount demanded is £67,163. A sum of £9,900 is to be paid for the purchase of two cables between England and Belgium, and £18,400 in consideration of four cables between England and France, and the cable between Jersey and France. The acquisition of offices, cable huts, and other buildings and furniture at London, Dover, St. Margaret's Bay, East Dean, and Jersey will absorb £27,413, and the remainder of the total will be swallowed up in fees and the purchase of engines, stores, and the telegraph ship. The telegraph administrations of France and Belgium are to pay £14,150 for one-half share of the property in the cables.

The Gwynne Electric Lighting Company.—We learn that this company has taken large premises in Leather-lane for central station purposes.

Obituary.—We regret to announce the sad death of Mr. C. J. Simmons, the well-known electrical instrument maker, on Thursday, 2nd inst.

Royal Society.—The following Paper was read yesterday before the Royal Society by Prof. E. Hull, F.R.S., "On a Possible Geological Origin of Terrestrial Magnetism."

Elieson Sale.—The piecemeal sale by auction of the Elieson Electric Company's plant, announced in our last issue, is, as will be seen by our advertisement columns, withdrawn until further notice.

Holyhead.—The Holyhead Local Board has resolved to give notice to the Gas Company to terminate the present contract, in order to be able to make new arrangements for the lighting of the town.

Electric Lighting on the Midland Railway.—In a few days the Midland Railway Company will have ready two trains fitted with the electric light. It is intended that they shall run between London and Liverpool and Manchester.

The Danish Cable.—The Fano-Calais cable has been interrupted near the mouth of the Elbe. This is the third interruption in two months, and, says *La Lumière Electrique*, "it is believed that malevolence is not altogether a stranger to these accidents."

Exeter.—The Exeter Electric Light Company has offered, to tradesmen first and private residents next, a supply of light free of charge for two months. Much progress has been made with the work of erecting the machinery at the central station in New North-road.

Telegrams between London and Paris.—On one day the week before last the number of messages between London and Paris despatched between the hours of 11 a.m. and 6 p.m. reached a total of 677, or 97 an hour. These are the highest figures yet recorded.

The Forthcoming Electrical Exhibition at Birmingham.—Mr. T. A. Edison has written to the manager of the Electrical and Industrial Exhibition, which is to be held in Bingley Hall in the coming autumn, that, if his engagements will permit of his leaving America this year, it will afford him much pleasure to accept the invitation of the Executive Committee to visit the Exhibition in Birmingham.

Central Station at London Bridge.—In connection with the London College of Electrical Engineering, a small central station has just been established at Denman-street, S.E. Its operations are at present confined to lighting two Turkish baths and the shops in the railway approach. Permission has been obtained from the owners of the numerous arches with which this part of London is honeycombed to run the cables in them.

A Warning.—On Wednesday evening a fire occurred on the premises of Messrs. Hepworth and Son, at Taunton, which are lighted by arc lights. As an advertisement the lamps remain alight two hours after closing time. About half-past nine on Wednesday evening the goods under one of the lamps were observed to be on fire, but before much damage was done it was extinguished. The fire was caused by a piece of red-hot carbon falling from the lamp upon the goods.

Woodhouse and Rawson (Limited).—It will be seen from the report of the directors of Woodhouse and Rawson (Limited), which we print on another page, that an agreement is to be submitted to the meeting of shareholders to be held this day (Friday), which arranges for the sale of the undertaking to a new company. The scheme met with the general approval of the shareholders at the meeting held on the 14th December

Digitized by Google

last. The terms of the agreement will be explained to the meeting, and we understand that the new company will be formed forthwith.

Cables of the Societe Francaise des Telegraphes Sous-Marins.—The following are the cables which belong to this company in the West Indies :—

Aquadores (Cuba) to Caymanera (Cuba)...	50	nautical miles.
Caymanera (Cuba) to St. Nicolas (Hayti)...	126	,,
St. Nicolas (Hayti) to Porto Plata (Hayti)	188	,,
St. Domingo (Hayti) to Curaçoa	453	,,
Curaçoa to La Guayra (Venezuela)	613	,,
Total	980	,,

The Suram Tunnel.—A correspondent writes from Moscow as follows :—"The electric light is in full operation at the above works, which are now making very rapid progress ; a considerable length of the inner brickwork has been completed from the side of Tispu Station and from that of the small town of Bey litz. Heavy falls of snow during the winter had retarded the work, but now that the electric light has been set to work by John Smith and Co., Moscow, under the superintendence of Engineer Tischko. the completion of the works have been taken up with renewed energy and success."

Telephone Trunk Lines in Germany.—At the end of 1888 the number of telephone trunk wires in Germany amounted to 166, having a total length of 10,607 kilometres, and over which a daily average of 28,099 messages were sent. The longest line is that between Berlin and Breslau, which attains a length of 348 kilometres, and over which some 100 messages pass every day. The Hamburg-Lübeck line is the busiest, having a daily average of 390 conversations, the Bremen-Bremerhaven wire coming next with 276 conversations per diem. The authorities have decided to erect 12 additional trunk lines during the current year.

Metropolitan Asylums Board Contract.—The following 13 tenders were received by the Asylums Board for the supply of an electric fire signal system at the School and Asylum for Imbeciles, Darenth, Kent :—Binko and Co , £749. 10s. ; F. J. Lovett, £625 ; Bailey and Grundy, £558 ; Strode and Co., £540 ; Julius Sax, £488 ; Wadley Bros., £473. 8s.; Co., Walker and Co., £438. 8s. ; Harrison and Co., £420 ; Blenheim and Co., £398 ; Fowler, Lancaster and Co., £369. 10s. ; Spagnoletti and Crookes, £348 ; Gent and Co., £333 ; Dale and Co. (Limited), Ludgate-hill, E.C., £318. The tender of Messrs. Dale and Co. (Limited), was accepted.

Royal Institution.—This Institution has recently received two important donations : Mrs. de la Rue has presented to the Royal Institution the philosophical apparatus of the late Dr. Warren de la Rue, which will be preserved there as the historical collection commemorative of the important scientific work of Dr. Warren de la Rue, and of the eminent position he has so long occupied as a promotor of science and of the special objects of the Institution. A fine portrait of Sir Humphry Davy has been presented by Mr. James Young, grandson of the late Dr. James Young, F.R.S., of Kelly, the distinguished chemist and former owner of the portrait. This is a valuable addition to the collection of historic portraits now in the Royal Institution.

Leeds.—At a meeting of the Electric Lighting Committee of the Leeds Corporation, held last week, the borough engineer (Mr. T. Hewson) submitted a report on a scheme for lighting by electricity the central portion of Leeds. He also submitted proposals and other details from two eminent firms who were prepared to contract for the lighting, the line being laid in Boar-lane, Briggate, Vicar-lane, Upperhead-row, and Albion-street. After consideration of the scheme the matter was adjourned for a fortnight to enable the engineer to submit alternative proposals with respect to the arc system of lighting as compared with the incandescent lamps, and as to the greatest distance the light can be delivered from the central station, which is proposed to be placed on the "Midden," at Leeds. The pressure proposed at Leeds is 2,400 volts.

Telegraphic Communication with the Orkneys.—Several meetings of the inhabitants of the Island of Westray, in Orkney, have recently been held regarding the want of telegraphic communication in the island. Westray is the largest of the north isles of Orkney, and has a population of over 2,000. There is an extensive fish trade, one curer alone having an overturn of about £10,000 per annum, large cargoes being shipped to foreign countries. The export of cattle is also great, valued at about £15,000 a year. There is a Post Office, Money Order Office, and Savings Bank, with only two mails in the week, without any telegraphic communication. The adjoining and less important islands of Sanday and Stronsay have telegraph offices. The matter has been brought under the notice of the Secretary for Scotland, the Postmaster-General, and the member for the county ; and it is earnestly hoped by the islanders that telegraphic communication will soon be established in Westray.

Friern Barnet.—At the last meeting of the Local Board of Friern Barnet, Mr. Hennessy proposed that the opinion of an expert should be obtained as to whether there was sufficient spare power in the engines at the Board's sewage works to drive dynamos for the lighting of the district by electricity, and what would be the cost of applying the engines to that purpose. He said the present price of gas—4s. 6d. a thousand feet—was enormous ; and as the machinery was sufficient to deal with the sewage of 40,000 people, and there were only 5,000 people in the district, there would appear to be a great deal of superfluous power. The Chairman seconded the motion on the insertion of a proviso that the expense of obtaining the opinion should not exceed five guineas. The Surveyor, in answer to Mr. Hennessy, said the engines could be used for the driving power for electric lighting if the number of revolutions and the amount of fuel were increased. The Clerk suggested that the opinion of Mr. Baldwin Latham could be obtained free of cost, and Mr. Hennessy agreed to defer his motion until the clerk shall have communicated with Mr. Baldwin Latham.

The Electric Light in Night Attacks.—An important experiment in night attack was made last Friday near Portsmouth, the primary object of which was to ascertain whether by means of the electric light it was possible to see and identify bodies of troops moving in the dark sufficiently well to fire at them. The objective points were Forts Grange and Rowner, forming part of the western defences guarding the land approach to the garrison and dockyard. As a colour test under the electric light, blue coats, red coats, and overcoats of various hues were worn. As soon as the men told off for the attack began to move a powerful beam was projected from the parapet of Fort Rowner, and it thoroughly exposed the positions, notwithstanding that the film of smoke produced by the defenders' own artillery crossed the ray. The red uniforms were very distinct, the least conspicuous colour being blue. What still further contributed to disclose the continually changing positions of the atacking force was the flash of the musketry and the jets of smoke from the firing, which, illuminated as they were under the electric beam, hung suspended like opaque clouds in the air.

Dublin.—The electric lighting License applied for by the Dublin Corporation was issued on May 9. The Corporation are now empowered to erect and maintain electric lines and works, and to supply electric light for "public purposes"—that is for public lamps and to public buildings in the city within the specified districts. There is no power to supply for private use. The following places are included :—Island Bridge-road, Sarah-bridge, Conyngham-road, Parkgate-street, Victoria-quay, Ellis's-quay, Arran-quay, Inns-quay, Upper Ormond-quay, Lower Ormond-quay, Bachelors'-walk, O'Connell-street, Upper and Lower ; O'Connell-bridge, D'Olier-street, Westmoreland-street, College street, College-green, Grafton-street, Dame-street, Parliament-street, Grattan-bridge, Capel-street, Moore-street, Henry-street. Electricity may also be supplied to public buildings along the streets and roads mentioned. Powers are given to lay the mains either overhead or underground, and two and a-half years is the period named for carrying out the project. The Corporation having now attained their object, it remains to be seen what will be done to give effect to the License. The matter will probably be discussed at the next meeting, and some decision arrived at as to the course to be adopted.

The Recent Thunderstorms.—Further details have now come to hand with regard to the numerous accidents and fatalities

Digitized by Google

resulting from the severe thunderstorms which occurred at the beginning of the month. Several houses and chimneys were struck in Glasgow and the vicinity. Fatal cases of lightning strokes are reported from Risca (Monmouthshire) and Bletchley. At Portsmouth one of the buildings on Whale Island, intended for the naval barracks, was struck by lightning, which tore off several hundred slates and did considerable damage to the interior of the structure. During a thunderstorm of peculiar severity which visited the Firth of Clyde the sun shone with exceptional brilliancy and the sea was as smooth as glass. Near Shrewsbury a flock of geese was destroyed by lightning. The birds, thirteen in number, were in the centre of a field when they were struck. Several were literally torn to pieces, and some were thrown a distance of sixty yards. At Kingsland (Herefordshire) a police superintendent and some men sought refuge from a storm in a small shed covered with corrugated iron roofing. The building was struck, the superintendent and another man were severely injured, and the contents of the shed, garden tools, axes, &c., were also damaged

Opening of a Central Station at Glasgow.—Messrs. Muir, Mavor and Coulson, who have been lighting the General Post Office of Glasgow and other buildings for some years past, have just formed a company in Glasgow under the name of Muir, Mavor and Coulson (Limited), for supplying light and power from a central station. The Ferranti transformer system is employed. The plant has been laid down in a central station near George-square. The engines, boilers and dynamos are on the ground floor, which has an area of 1,400 square feet. There is at present fixed a large steel boiler working at 100lb. pressure, and a compound horizonal tandem engine of 200 indicated horse-power driving a Ferranti dynamo capable of lighting 3,000 lamps of eight candle-power. There is accomodation for two more similar boilers and engines. An auxiliary engine of 50 indicated horse-power has also been erected, together with a Siemens alternating dynamo capable of lighting 500 lamps. At present, therefore, the installation can supply 3,500 eight candle-power lamps. Sir William Thomson's newest measuring instruments are used. Among the more important undertakings of the Company we may mention the contract with the Corporation of Glasgow for lighting the new municipal buildings, where 1,100 16 candle-power lamps will be fed from the station. Consumers can be supplied by meter at the rate of 8d. per 1,000 watt-hours. Considering the cheapness of gas in Glasgow, we congratulate the Company upon having made such a good start

The London Central Subway Bill.—The Bill for the construction of an electric railway subway between Holborn-circus and Piccadilly came before a Select Committee of the House of Commons on Thursday last week.

Mr. Littler, Q.C., said that the resonance feared from the large quantity of metal used in the construction of the subway would be removed by the use of a material known as fer-flax, composed of iron and vegetable fibre shreds, which would be compressed and packed as panelling between the metal pillars of the subway. Galleries would be provided for pipes and wires. The carriages would be long cars on the American system, each holding about fifty passengers. A system of deflecting plates would keep a derailed train going along until stopped by the brakes, which would be magneto-electric. The trains would run every two minutes, and at a greater speed than on the underground railways. Contractors were prepared to construct the subway for £350,000. Colonel Hazard, one of the promoters, was examined, and the committee adjourned.—On Monday evidence for the promoters was continued, Mr. Harrison Hayter, C.E., in the course of his examination, stating that the width of each train would be 8ft. 2in., the cars being of a size to give 6in. clearance on each side and above, and, acting thus as a piston, would insure ventilation without the blowholes to which objection had been raised in the underground railways. He was of opinion that the subway could be constructed well within the estimates. On Tuesday the Bill was further considered, the evidence of engineers in support of the scheme being proceeded with. The engineer to the scheme, Mr. Knight, said that the electrical motors would be used at each end of the train, one pulling and the other pushing. They would be able to go up to twenty miles an hour in speed, but the average would be twelve. Mr. R. E. Crompton, Dr. Hopkinson, and Sir William Thomson gave evidence in support of the scheme being practicable in their opinion. Mr. W. H. Preece said that the current in the mains would not interfere with the telephonic and telegraphic wires, and the galleries proposed for them would be ample and convenient. Evidence was given as to the working cost per train-mile being about 1s. 6d. Mr. Pope, Q.C., then announced that evidence in opposition would be called by the London County Council.

The Halifax and Bermuda Cable.—In the House of Commons on Thursday last week Mr. Jackson moved that the contract for the construction of a submarine telegraph line from Halifax to Bermuda be approved. The question, he said, had been considered by successive Governments, and all had agreed in the necessity of establishing telegraphic communication between Halifax and Bermuda. The House, therefore, had only to consider whether the terms of the contract were such as should be accepted. The Government had taken unusual precautions to provide for the ample and complete security, not only of the construction, but of the maintenance of the cable. The subsidy of £8,100 which it was proposed to pay would only be payable from the time when the cable was first in working order, and only as long as it was so maintained.—Dr. Cameron moved an amendment to the effect that the telegraphic communication between Halifax and Burmuda would have been better and more economically established by means of a cable to be laid down and maintained by Her Majesty's Government. It was stipulated in the contract that the capital of the company should be at least £100,000, and that the amount expended in laying the cable should be not less than £80,000. But the sum they were asked to pay (£8,100) represented, if capitalised at 3 per cent., a capital of £230,000 or £240,000. The fact was they were undertaking to pay a perpetual subsidy which represented a capital of £250,000.—Mr. Henniker Heaton believed that the contract as such was a good one. But his objection to the proposal was that the British Government should cease paying subsidies.—Mr. Jackson said if the amendment were adopted it would involve the Government in an additional cost of at least £5,000 a year. With regard to the question of rates, the Government messages were to have priority over all other messages at rates to be sanctioned by the Treasury. He believed that the usual rate was 4s. a word.—After some further discussion the amendment was lost and the original motion was agreed to.

Passenger Telpher Lines.—We are informed that the United Electrical Engineering Company (Limited) have just closed a contract with the Mines and General Telpher Company (Limited) for the equipment of a Telpher Line to convey visitors from the Wood Green station up the hill to the Alexandra Palace. The Palace seems to have entered upon a prosperous era, and it is confidently anticipated that the coming season will be a specially successful one. The Wood Green entrance is that by which a very large proportion of the visitors enter the grounds, and the line is for the purpose of conveying them from thence to the Palace and back. The simplicity and economy of electrical traction, our correspondent says, "is likely to cause very great extensions in the equipment of light railways and tramway lines between towns and outlying suburbs and villages which are not yet provided with carrying accommodation; and the great practical development of telpherage initiated by the Palace Line will doubtless command for the system a very great deal of attention. Even in the United Kingdom, where transport requirements may be said to be much better provided for than in other countries, a considerable amount remains to be done. A glance at the maps of either of the three kingdoms will show that large tracts of productive country are unprovided for, so that producers and the travelling public are placed at a considerable disadvantage in competing with those who are more fortunately situated. As has been pointed out by Mr. A. R. Bennett in respect to Scotland, it would certainly not pay to open up most of these districts by means of the ordinary steam railway, even if single tracks and light engines were adopted, but they might profitably be exploited by means of Telpher lines or electric tramways laid either on the public roads or close beside them. In the case of the Colonies and abroad of course the field is enormous, and it would seem that the Telpher system may be a powerful factor in leading to the development of countries which either do not possess capital enough to build railways or even to make common roads, or have not sufficient traffic to justify a large expenditure."

THE EDISON EXHIBIT AT THE PARIS EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT).

PARIS, *May* 15, 1889.

The Edison exhibit forms a most important and attractive display, the more so as it is already practically complete. No one who examines this remarkable display can fail to be struck with the wonderful versatility displayed in the inventions of Mr. Edison. That one man alone should be the originator of no less than 493 patents, besides the 300 more applications for patents in his name which are still pending, is marvellous enough, but the wide range of applications covered by the patents is still more astounding. The exhibits comprise the most recent apparatus in all the leading branches of Mr. Edison's inventions, and may be classed under the following heads:—Telegraphic, Telephonic, Phonographic, Physical, Electric Lighting, Underground Conductors, Lamp Manufacture, the Electrical Separation of Metals, and Electric Meters. We will first take a rapid glance at the principal objects of interest, deferring a more detailed examination until a later date.

In the Telegraphic Section we find at work the latest bridge quadruplex system, now adopted in this country; the Duplex system, the Phonoplex system of signalling, in which a form of telephone is used as a sounder; train telegraphs, the automatic telegraph, by which a speed of 1,500 words per minute has been obtained. The last-named instrument is capable of transmitting either Roman letters or Morse characters, the former requiring five and the latter three wires. The five-wire system is the most generally adopted, the message being put into the transmitter by a punched slip moving over a metal roller. The roller is rotated rapidly by an electric motor, and the contacts between the battery and line are made through the perforations in the slip. At the distant end the currents produce by chemical action corresponding symbols to those transmitted. This system was operated for some years between New York and Philadelphia and New York and Washington by the Automatic Telegraph Company and the Atlantic and Pacific Telegraph Company; and later, upon the absorption of these companies by the Western Union, it became the property of the latter. There are also exhibited the Harmonic Telegraph, Stock Printers, District Messenger System, Motograph Relay, Carbon Relay, and Rheostat. The motograph relay, which operates a local sounder or Morse circuit, is a marvel in itself. The contact closing the local circuit is attached to a spring resting on a rotating chalk cylinder, and the principle of the reduction of surface friction between the spring and the cylinder on the passing of a current through them, which was applied by Mr. Edison to his loud-speaking telephone, is here applied, the spring responding in lateral movement to the successive currents received. The cylinder is driven by a small electric motor with worm gearing, rendering the instrument, therefore, self-contained. In illustration of the same principle we find several instruments in the Physical Section which have been made specially for the show, amongst which we may mention one in which the experimenter holds a brass spring with a palladium tip, and slides the tip along a surface composed of blocks of various metals in succession. The current being passed through the metallic surface and the spring, a difference can be felt in the surface friction according to the different metals in contact with the spring. In this Section also there are experimental incandescent lamps fitted with a central platinum wire between, but not touching the sides of the carbon filament, to show the "Edison effect," which is, that while the lamp is burning, a galvanometer, or even a sounder, inserted between the positive terminal of the lamp and the isolated platinum wire is actuated every time the sounder circuit is closed. In this Section is also shown the megophone, which is an apparatus for concentrating waves of sound and rendering speech possible at a distance of three miles. There are two large cone-shaped receivers, 7ft. long, and tapering down from 2½ft. diameter at one end to 1in. at the other. A speaking-trumpet, with an orifice 6in. diameter, is fixed between the two receivers.

In the Electric Lighting Section is exhibited a complete central station plant on the three-wire system. Everything will be installed according to the latest methods. The two similar dynamos to be run with this station are each of 125 volts and 240 amperes, and run at 1,200 revolutions. Each machine weighs 4,340lb. The machines are shunt-wound, and can be regulated as to their potential by an adjustable resistance inserted in series with the shunt wire. The three mains, or "omnibus" wires, are conducted from the machines to the distributing board, whence the connections to the various feeders are made.

These details of the central station system really demand separate treatment, and we must defer our description until we can enter exhaustively into the subject with the aid of diagrams. For the present we may say, however, that the underground conductor system is very fully shown, the conductors leading from the central station actually being laid down in pipes according to the latest method. Mr. Edison's original method was to inclose the bare copper mains in iron pipes, and retain their distance apart by passing the mains through pieces of thick millboard placed at intervals along the pipe. It was found, however, that it was necessary to connect together the millboard supports by string, in order that they should retain their relative positions during the running in of the insulation compound. The improvement effected and now employed consists in wrapping each conductor of bare copper round with a separate spiral of rope, which acts as a separator between the mains, and afterwards an outer wrapping of rope round the outside of the conductors, which keeps their position central in the pipe and separates them from contact with it.

The process of lamp manufacture and the Edison electrolytic meter system is shown in great completeness by means of specimens of the actual materials throughout the various stages.

Mr. Hammer, to whom the design of the huge model Edison lamp and the flashing effects in incandescent lamps which are to be exhibited on its pedestal are due, intends, we are glad to hear, to reproduce the marvellous effect of transformation of sound through the medium of two Edison phonographs, two carbon telephones, two motograph receivers, and two induction coils, which he demonstrated with such success at his lecture in the Franklin Institute, Philadelphia, between that place and New York.

I may mention that over the American Section, in the Machinery Hall, an inscription has been put up stating that the United States possess steam engines of 450,000 horse-power, the power of which is transformed into electrical energy; and that, apart from transmission of power, this energy is used to supply current nightly to 2,000,000 incandescent lamps and 250,000 arc lamps.

The conduits which are being laid along the Boulevards from the Porte St. Denis to the Grand Hotel by the companies which have obtained the contract for the lighting of the Boulevards are now practically completed. These conduits are 1·5 metre high and 75 centimetres broad, and are laid under the pavement on either side; transverse conduits under the roadway connect the two lines at intervals. The conductors are uninsulated, being merely suspended from porcelain insulators. The lighting of the Place de l'Opéra commenced the day the Exhibition opened, and that of the chief Boulevards will shortly follow.

The municipal central station at the Halles is progressing rapidly. The foundations for the steam engines are nearly completed, and the chimney is now being built. The Municipal Council have just voted £8,000 for the distributing mains. The President of the Republic has just had an installation of 1,600 10 candle-power lamps put into the Elysée, the current being derived from a 2,000-volt transformer circuit, run from the Edison station at the Palais Royal. The plant devoted to this installation comprises an old type Zypernowski dynamo of 160 horse-power, driven by a Weyher and Richemond engine, besides two 60 horse-power machines. These dynamos are excited by the continuous current supplied by the station. The current is taken to the Elysée by means of a concentric armoured cable, manufactured by the Société Générale des Telephones, and laid partly in a trench and partly in a sewer. The whole installation was executed in a week—a "*beau fait d'armes*," as the daily press terms it.

THE USE OF THE INTEGRAPH IN DETERMINING SOME PROBLEMS IN ELECTRO-DYNAMICS.

BY L. B. ATKINSON.

(Concluded from page 731.)

The problems treated in the two previous articles have depended on no physical assumptions beyond certain fundamental electrical equations, and their solution by means of the integraph introduces purely kinematical principles. The question now to be considered involves one of the most burning questions of electro-magnetic science; one on which a great deal has been written, and for which many approximate formula have been devised, and it only remains to show that by means of the integraph the question may be probably more nearly solved than in any other way.

The problem is—given a magnetic circuit composed principally or entirely of iron, given also the magnetic force acting, what is the nature of the function which expresses the relation between the magnetic force and the induction?

The formulæ which the most prominent writers on dynamo machine construction have adopted are as follows:—

Prof. S. P. Thompson:

$$H = \frac{G \kappa N C}{1 + \sigma N C},$$

where H is the induction, σ and κ certain constants, and N C the number of ampere turns.

Frölich uses a similar formula:

$$H = \frac{C}{a + b C},$$

where C is the current and a and b certain constants.

Kapp's most recent formula is

$$H = a N C \frac{\frac{\pi}{2}\sigma}{\tan \frac{\pi}{2}\sigma},$$

where a and σ are again constants.

These equations are all used only as approximations convenient from their comparative simplicity for purposes of calculation and graphical representation.

The formula of Lamont rests on certain physical assumptions which, reasonable in themselves, are justified by the fact that the function expressed more nearly corresponds to the facts than any of the preceding. His assumption is this. There is a certain maximum possible induction through any piece of iron. The ratio of magnetising force to induction, or permeability, for every value of the magnetisation depends on the difference between this value and the maximum, or in symbols

$$\frac{dm}{dc} = k(M - m),$$

where M is the maximum value of the induction m.

It has been remarked that the approximate formulæ before given are all reducible to formulæ composed of the first one or two powers of the series into which Lamont's exponential formula can be expanded.

But the integraph described in Fig. 2, *Electrician*, page 702, at once draws the curve expressed by this formula completely, without any approximations. Taking the usual nomenclature of the magnetic circuit, let M be the maximum possible induction, let ρ be the initial magnetic resistance, and m the induction, and n C the ampere turns—

$$m = \frac{\cdot 4 \pi n}{\rho} \text{ F (C) where F (C)} = (M - m) C;$$

hence,

$$\frac{dm}{dc} = \frac{\cdot 4 \pi n}{\rho}(M - m).$$

In Fig. 1 set the bar $b\,b$ at a position such that $h\,o = M$ the maximum induction, set g so that $h\,g = \frac{\rho}{\cdot 4 \pi n}$, then on moving the integraph frame parallel to the axis O X, representing the abscissæ of the current, the integraph wheel follows the curve (m.C) and

$$\frac{dm}{dc} = \tan\theta = \frac{h\,o - o\,e}{h\,g} = \frac{M - m}{\frac{\rho}{\cdot 4 \pi n}} = \frac{\cdot 4 \pi n}{\rho}(M - m),$$

the required curve.

The fact that the magnetic curve can be thus drawn so conveniently suggests the fact that an integrator can be constructed in which the relation of parts is so arranged that the characteristic curve of series or shunt machines could be at once drawn mechanically for any design by proper setting of the parts. It is not worth while here to enter into the details, as the use of such apparatus would be very limited; but a more important application is in the determination of the current in, say, a solenoid with a closed iron magnetic circuit under the influence of an alternating E.M.F. The integraph (Fig. 1) does this when the coefficient of self-induction is constant; but the coefficient of self-induction is not constant. By definition, $\frac{L}{n} = \frac{dm}{dc}$, which has been shown to be expressed by the equation $\frac{\cdot 4 \pi n}{\rho}(M - m)$, and hence the distance $h\,e$ is at any value of x the current proportional to the coefficient of self-induction.

Fig. 7 shows an integraph to draw the curve of current in a circuit enclosing an iron magnetic circuit when the E.M.F. varies according to any law given.

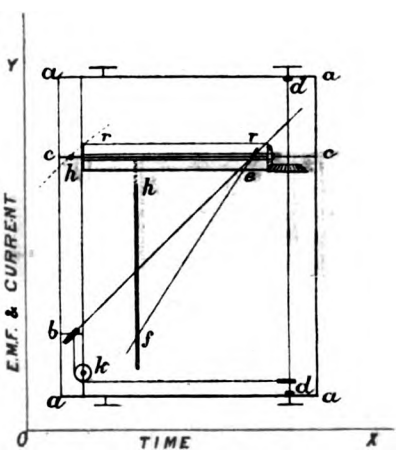

FIG. 7.

$a\,a\,a$ is the frame, b the main integrator and slide; instead of the simple cross-bar of Fig. 1, a cross-slide, $c\,c$, is provided, moving up and down, carrying with it a roller, $r\,r$, which is geared by a pair of bevel wheels, one of which slides with a feather on the shaft $d\,d$, which is driven by the roller d, which has wound on it a cord passing round a pulley and fixed at b, so that the surface of the roller r travels as the frame b moves in the direction O Y, in a ratio fixed by the dimension of d.

The rotating pillar at e instead of being fixed, slides in $c\,c$, being controlled by a second integrating wheel e, guided by a tiller $e\,f$, f being a rotatory point on $h\,f$. (Note.—In the figure, to avoid several lines coinciding, h_1 has been drawn at one side of its true position; h_1 should coincide with h if the self-induction of the wire apart from the core be neglected.)

The initial setting is as follows:—

The pulley at d is of such size that it transmits the motion of b to the surface of the roller r in such a ratio that if $d\,s$ be the element of movement of the surface of the roller,

$$d\,s = \frac{\cdot 4 \pi n}{\rho} \times d\,c,$$

where n is the number of turns in the coil and ρ is the magnetic resistance of the core, $h\,e$ is set equal to $\frac{\cdot 4 \pi n}{\rho} \times \frac{n}{R} \times M$, where M is the maximum possible induction.

Also $h\,f = 1$.

If x be the movement of e from its origin, and $h\,e_1$ the new length of $h\,e$,

$$\frac{dx}{ds} = \frac{h\,e_1}{h\,f} = \frac{h\,e - x}{h\,f} = \left(\frac{\cdot 4 \pi n}{\rho} \times \frac{n}{R} \times M\right) - x;$$

Digitized by Google

and if $$x = m \times \frac{\cdot 4\pi n}{\rho} \times \frac{n}{R},$$

$$\frac{d}{ds}\left(\frac{\cdot 4\pi n}{\rho} \times \frac{n}{R}\right) m = \frac{\cdot 4\pi n}{\rho} \times \frac{n}{R} M - \frac{\cdot 4\pi n}{\rho} \times \frac{n}{R} m,$$

or $$\frac{\cdot 4\pi n}{\rho} \times \frac{n}{R} \times \frac{dm}{ds} = \frac{\cdot 4\pi n}{\rho} \times \frac{n}{R} (M - m);$$

but substituting for ds is equivalent value as above, and reducing $$\frac{n}{R}\frac{dm}{dc} = \frac{\cdot 4\pi n}{\rho} \times \frac{n}{R}(M - m);$$

hence $\frac{dm}{dc} = \frac{\cdot 4\pi n}{\rho}(M - m)$, and the curve of magnetisation is satisfied; but $L = \frac{n\,dm}{dc}$,

$$\therefore \quad \frac{L}{R} = \frac{n}{R}\frac{dm}{dc} = \frac{\cdot 4\pi n}{\rho} \times \frac{n}{R}(M - m) = \frac{he_1}{hf} = he_1,$$

and the integrating wheel b follows the curve represented by

$$\frac{dc}{dt} = \frac{bh}{he_1} = \frac{\frac{E}{R} - C}{\frac{L}{R}}$$

which reduces to the equation

$$L\frac{dc}{dt} + CR = E,$$

the current curve, where L has been shown to follow the variation of magnetism with variation of C.

Fig. 8.

One more electrical problem only will be alluded to, though others might be added. Suppose an alternating or variable E.M.F. acts on a circuit (Fig. 8) not closed but connected with a condenser of capacity K through a circuit of resistance R and coefficient of self-induction L. The current equation is

$$L\frac{dc}{dt} + CR = E - V,$$

where V is the potential difference between the condenser plates, and $$\frac{dV}{dt} = \frac{C}{K}.$$

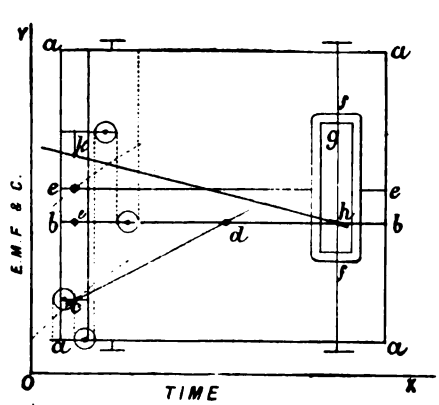

Fig. 9.

Fig. 9 shows the integraph adapted to draw the curve of current to satisfy these equations. The framework $a\,a$ carries the integraph wheel and slide c, and tiller $c\,d$, connected to another slide, whose position is controlled by being the carrier of a second integrating wheel h, which runs on the surface of a roller g. This roller is carried in the frame and slide $e\,e$, which carries the tracer e following the curve of E.M.F. The roller slides on and is driven by the feather shaft $f\,f$ carried by the guide rollers, so that the surface of g moves the same distance as the frame $a\,a$ moves parallel to O X. The curve of E.M.F. and time is drawn to the scale $e = \frac{E}{R}$.

The integrating wheel h is guided by the tiller $h\,k$, k being a point moving with the point c, so that $k\,b$ equals the ordinate of c. This movement is effected by two pairs of pulleys and a cord, as described in an earlier example.

The setting of the parts is thus $l\,h = K\,R$, $l\,d = \frac{L}{R}$, and h starts on the line $e\,e$.

The ordinate $e\,b$ moves so that $\frac{d}{dt}(e\,b) = \frac{k\,l}{l\,h} = \frac{C}{K\,R}$, and calling $e\,b$, $\frac{V}{R}$ then $\frac{1}{R}\frac{dV}{dt} = \frac{C}{K\,R}$, which satisfies the equation of the potential between the condenser plates.

The wheel c traces the curve

$$\frac{dc}{dt} = \frac{cl}{ld} = \frac{ol - C}{\frac{L}{R}} = \frac{e - eb - C}{\frac{L}{R}} = \frac{\frac{E}{R} - \frac{V}{R} - C}{\frac{L}{R}},$$

or $$L\frac{dc}{dt} + CR = E - V,$$

which is the required curve showing the current variation in the circuit.

These cases chosen will suffice to show the adaptability of integraphs of this class to the solution of a large number of electrical problems perfectly generally, which in the ordinary way can only be solved with readiness in certain special cases, or assuming a very simple law of variation of impressed E.M.F.

ELECTROLYTIC DISSOCIATION.

ANSWER TO MESSRS. J. BROWN AND O. LODGE.

BY PROF. W. OSTWALD.

In *The Electrician* of the 19th of April, 1889, there appear two attacks on a Paper by me concerning electrolysis. In the first place Mr. J. Brown objects to the term "free ions," because Faraday's views about their motion during electrolysis were different from mine. At present, however, by "ions" is quite generally understood those parts of the electrolytic molecules which on the passage of the current move in opposite directions. I assume with Arrhenius that these parts are separate from each other in an electrolytic solution, even when a current is not passing, and call them consequently *free* ions. This seems to me to sufficiently denote the difference between my conception and the older one.

As for the experiment to which Prof. Lodge draws attention, I may shortly refer to the history of the whole matter. In the discussion which followed the publication of the theory mentioned above, the objection was often raised that it was impossible to admit the existence of (*e. g.*) free potassium atoms in a solution of potassium chloride. To refute this objection I described an *ideal experiment*, the same to which Prof. Lodge refers. If he had troubled himself to give a translation of the *whole* passage in my Paper (*Zeitsch. f. Phys. Chemie*, 2, 271, 1888), he would not have fallen into the error of mistaking a mere *scheme* used for the purpose of demonstration for an experiment actually carried out.* The passage in question begins with the words, "To get a clear idea of the conditions which here obtain we may imagine the following 'self-evident' ('*selbstverständlich*') experiment carried out. Two vessels," &c., &c.

With the same irritation with which Prof. Lodge charges me with scientific immorality I might bring a similar charge against him, for it is surely no less "a matter of simple morality" to acquaint oneself previously with the contents of a

[*As will be seen from a letter in our correspondence, Dr. Lodge has independently discovered the fact here pointed out by Dr. Ostwald.—Ed. *E.*]

Digitized by Google

Paper against which one has entered into a polemic than it is to describe one's experiments with exactness. However, I will not return like for like, but willingly assume that I have not expressed myself sufficiently clearly for Prof. Lodge.

It may be asked if I was justified in describing such an experiment as self-evident. If, first, it be assumed that the laws of electrostatics apply to electrolytes, and, secondly, if the correctness of Faraday's law is granted, then it appears to me impossible to deny the presence of an excess of potassium atoms in a positively charged solution of potassium chloride. Prof. Lodge has questioned neither of these premises, and so will surely accept the conclusion drawn from them.

Besides, an experiment completely comparable with the above scheme has been executed by Soret, and is described in a generally accessible work (Wiedemann's "Elektricität," 2, 469). I confess that I neglected to mention this expressly, and did so because I believed that my two premises were so beyond all doubt that further experiments for their confirmation were not necessary. The last thing, however, that I should have expected was that Prof. Lodge, who has devoted himself with such success to the study of electrolysis, should be in ignorance of this experiment.

Prof. Lodge is thus perfectly right when he declares his conviction that the experiment has not been carried out in the form given by me. But he might have come to the conclusion in a much shorter way, namely, by carefully reading my original communication. Though not done in this form, the experiment has nevertheless been performed in a perfectly equivalent one, and if Prof. Lodge wishes it I will describe to him with pleasure an arrangement by means of which the experiment may be successfully executed in a form corresponding to the scheme.

As doubts were also elsewhere raised as to the absolute validity of Faraday's law, I made, along with Dr. Nernst, some experiments which have proved these doubts to be utterly without justification. I send a copy of the Paper to the editor of *The Electrician*, and should be thankful if in the interest of the matter a translation were published in that journal.*

A word in conclusion to Mr. J. Brown (of Belfast). I have endeavoured to penetrate into the mechanism of electrolysis by studying the movements of the electricity and its ponderable bearers, the ions. Mr. Brown finds this analysis unnecessary, for, as he says, the separation of the ions in the experiments described by me is caused "by the usual electrolytic phenomena."

Mr. Brown (of Belfast) has solved the problem of electrolysis: according to him electrolysis is—electrolysis.

Leipsic, May 3, 1889.

THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 11th inst., Prof. O. J. Lodge, F.R.S., read a Paper

"On an Electrostatic Field, produced by Varying Magnetic Induction."

Prof. Lodge observed that in common with other experimenters he had often tried to find some connection between static electricity and magnetism, and to illustrate his ideas on the subject he described the following experiments, selected as typical examples from a large number which had suggested themselves to him as likely to throw light on the question :—

1. Spin a long bar magnet on its axis; suspend in its field a sort of quadrant electrometer needle charged oppositely at either end, and look for a deflection.

2. Construct a cylindrical or drum-shaped horse-shoe magnet resembling a pair of iron wheels joined by their naves and wound with wire, spin it on its axis, suspend a charged pith ball between the two rims, and observe what effect, if any, is produced on the ball.

3. Use a varying electro-magnet instead of a moving magnet (an idea for which the author was indebted to Prof. Fitzgerald), suspend some electrified substance—as, for example, a charged gold leaf—between the pole pieces, and see if the leaf moves backwards and forwards when the current is stopped and started.

Prof. Rowland's classical experiment of deflecting a magnetic needle by means of a rotating charged disc, which he has recently repeated so successfully, can hardly be considered to establish a connection between electrostatics and magnetism. What he has shown is that convection currents of electricity exert magnetic effects like any other electric currents. The experimental results which the author was looking for would not, therefore, be exactly the converse of Rowland's experiment, but would be closely related to it. He was in hopes of being able, by some such method as those indicated, to obtain a crucial criterion between Maxwell's theory and some of the contemporary German theories.

The author stated that when Mr. Chattock became a demonstrator in the physical laboratory of University College, Liverpool, two years ago, he found that he was interested in the same subject, and that his ideas with regard to experimenting on it were more practical than his own. Mr. Chattock considered that it was unnecessary to suspend the charged body in a magnetic field, and that varying magnetic induction in a region near the charged body was all that was required. He suggested the use of a closed magnetic circuit, including all its lines of force within itself, and that the charged bodies should be hung outside and close to the circuit, so that as long as the magnetic induction was steady no lines of force would pass through the charge, but when it varied they would move past the charged body, and possibly produce the desired effect. The theory of the results under consideration is as follows :—

If I is the magnetic induction through a circuit the E.M.F. excited in the circuit when I changes is $E=\frac{dI}{dt}$. Now, if an E.M.F. acts on a body carrying a static charge, Q, at a distance, r, from the centre of the solenoid, the work done in making it take one turn is $EQ=F.\,2\pi r$, where F is the mechanical force exerted on the charged body. If, however, the E.M.F. is of the form $\frac{dI}{dt}$, it will only last for a very short time, and we must therefore consider the impulse of the force, namely,

$$\phi=\int_0^\infty F\,dt=\frac{IQ}{2\pi r},$$

and this is the momentum generated when the magnetism of the solenoid is excited or allowed to die away.

This, therefore, or some multiple of it, is what is observed in the experiments. Now with the usual notation,

$$I=\frac{4\pi n C A \mu}{l}=\mu l\times \text{a length, and } Q=KV.$$

Thus the product IQ contains the factor μK, which is the reciprocal of the square of the velocity of light. It follows, therefore, that the observed effect must necessarily be extremely small. Prof. Lodge then observed that in a Paper read before the Society of Telegraph Engineers two or three years ago,* Prof. George Forbes, in considering analogies between magnetic and voltaic circuits, had given almost exactly the arrangement which he had found successful as a magnetic analogue to the tangent galvanometer. Dr. Lodge then described the experiment in the form in which he had last made it.

He takes a large hank of iron wire, weighing some 28lb., covers it with tape, and winds it over with No. 14 silk-covered copper wire, which is then connected through a reversing key with a storage battery or series of ordinary cells, preferably the former. At the centre of the ring is placed a glass vessel containing a delicately suspended apparatus consisting of two oppositely charged conductors of aluminium foil, connected with each other and with a mirror by an arm of shellac. The reversing key is then worked by hand at the same rate as the natural period of vibration of the suspended arm, so as, if possible, to get up a swing. After carefully eliminating electrostatic effects, it was found that with this apparatus no sensible effect of the kind sought for could be obtained.

In his further attempts the author experienced a great deal of difficulty from the substance employed for the conductors being invariably found to be slightly magnetic, and from Foucault currents being set up in the mirror. He finally employed as conductors small cylinders made of thin gelatine, very similar to that which is used to wrap round crackers; and, indeed, in some of the earlier experiments this material was actually employed.

The Foucault currents in the mirror were partially got rid of by scoring the metallic surface with lines, but in his latest experiments he gave up the mirror entirely and used a pointer and reading microscope. The ring was also made much more carefully, of exceedingly fine iron wire, uniformly wound. The Professor then began to entertain some doubts of the effect of the copper near the needle, and sheet copper was used to screen it off from the wire, and also all over the outside of the arrangement so as to screen off electrostatic action; he then, however, came to the conclusion that when this was done the motion of the electricity in the conductors was of the same sign as that of the electrostatic charge which was being looked for, and therefore the reaction of the charge

[* We hope shortly to publish a translation of this Paper.—Ed. *E.*]

* See *Electrician*, December 17, 1886, p. 129.

Digitized by Google

momentarily redistributed on the conductors might possibly mask the direct effect of the E.M.F. acting on the charged body. On the other hand, by arranging a copper conductor so that the effect of electric charges induced in it by the E.M.F. should assist the direct effect of the E.M.F. on the charged body, it appeared very likely that the deflection might be rendered visible. A short wire was therefore wound round the outside of the ring and its ends were brought into the box containing the needle, one on each side of it. A distinct deflection of the kind expected was then observed. Ten turns of wire were then used, and a much more marked deflection was obtained.

The author considers that this method would furnish a good means of determining the value of "v," and "v^2" is actually measured in it. What the author wanted, however, was to observe the effect in a free dielectric without the assistance of the conductor, and he succeeded at last in doing this. All copper screens and everything of the kind were removed. A few turns of thick wire were wound on the ring so as to reduce the slope of potential in it. The wire was then wound symmetrically in two halves, and the far ends were connected to a plug key, so that the observer could work either on closed or open circuit. The middle of the battery was put to earth, so that the potentials of the two halves of the wire might be equal and opposite, and the needle was then adjusted by trial and error, the glass box being pushed in and out of the ring, and the suspended fibre turned by a tangent screw until the electrostatic effect obtained by reversing on open circuit was very small. It could never be got down to zero, and even when small it would not always remain so for long. However, if the circuit was now closed by the plug key the electrostatic effect would certainly be largely reduced, and the effect looked for might possibly be seen. This was found to be the case.

The spot of light oscillated over 2 or 3 millimetres when the key was worked in unison with the vibrating arm, so as to assist the electrostatic effect. When the charge of the needle was reversed, the deflection was either neutralised or reversed. This reversal of the electrostatic effect affords, in the Author's opinion, conclusive evidence of the correctness of the observation. Prof. Lodge exhibited a hank of iron wire wound over with tape, with several secondaries wound round it, consisting of copper wire of various thicknesses, and of one or several turns, and he showed that when an alternating current was made to traverse the primary copper circuit the amount of current passing was considerably increased when the circuit of one of these secondaries was closed; the reason being that the impedance of the circuit was greatly reduced, becoming, in fact, nearly zero. The heating of the secondary in the case of a single turn of moderately thick copper wire by the currents induced in it was very effectually shown by wrapping round it a little gun-cotton, which was ignited a few seconds after closing the primary circuit.

DISCUSSION.

In the discussion which followed the reading of the Paper—

Prof. FITZGERALD observed that it would be exceedingly difficult to detect experimentally the existence of an effect depending upon $\frac{1}{v^2}$. He suggested that Prof. Lodge should calculate the momentum which ought to be given to the needle according to theory, and compare it with that which he observed. With such small quantities of electricity as were employed in Prof. Lodge's experiments he would have thought the momentum too small to be sensible. He had himself thought over experiments of the same character for many years, and when the subject first engaged his attention he was only prevented from carrying out his ideas by having no means of suspension sufficiently delicate to give any hope of success. Now, however, this was no longer the case, thanks to Mr. Boys. He stated that Dr. Lodge had not exactly grasped his meaning with regard to the motion of a charged conductor—a piece of gold leaf, for example—between the poles of an electro-magnet, the polarity of which was rapidly alternated. He did not think that a body placed in this position would move backwards or forwards as supposed by Prof. Lodge. He expected that it would rotate in its own plane—that is to say, in a plane perpendicular to the lines of force. He observed that some years ago he had pointed out some modifications which he considered ought to be introduced into Maxwell's general equations of the electro-magnetic field. Maxwell gives the equation

$$P = c\frac{dy}{dt} - b\frac{dz}{dt} - \frac{dF}{dt} - \frac{d\psi}{dx},$$

where P is the x-component of the E.M.F., F the x-component of the vector-potential, and ψ the electrostatic potential. Maxwell's equation for the mechanical force acting upon a circuit carrying a current in a magnetic field, viz.:—$X = v\gamma - w\beta - e\frac{d\psi}{dx}$ + a term depending on magnetism,—should be modified by replacing the term $e\frac{d\psi}{dx}$ by eP. This gives the term

$$e\left(c\frac{dy}{dt} - b\frac{dz}{dt}\right),$$

corresponding to Rowland's effect, and $-e\frac{dF}{dt}$, representing the effect which Prof. Lodge was looking for. He pointed out that there was no analogue to this in the magnetic equations, because there was nothing in magnetism analogous to an electric charge or to an electric current. The flow, as it was called, of the lines of magnetic force, was the analogue, not of a current of electricity, but of the flow of induction in a dielectric, and there was nothing in magnetism analogous to a conductor of electricity.

Prof. S. P. THOMPSON stated that since his last communication to the Royal Society he had made an experiment which had not yet been published, and might be of interest in connection with those described by Prof. Lodge. He had wound copper coils upon rings built up of iron wire—Gramme rings, in fact—and caused an alternating current to traverse the copper coil; then, placing an ordinary Bell telephone receiver in the circuit, he had endeavoured to discover conjugate positions of the second ring with respect to the first, in which the telephone in the second circuit would remain silent while the alternate current passed through the first. He had been unsuccessful in this, having only been able to find positions of minimum noise, even in the case of one ring being placed inside the other, with their planes at right angles. He thought that this was probably due to some of the special properties of iron. When a conductor of any kind was placed within the system of two rings at right angles, such as a rod partially threaded through them, or even a brass ball, it caused a disturbance. This he believed to be due to the oscillations in the conductor. If in place of the conductor a closed circuit were threaded through both the rings, such a disturbance would necessarily be set up by the alternating currents generated in it. He had tried the effect of introducing a dielectric, such, for example, as a rod of Faraday's heavy glass, which he had selected on account of its high specific inductive capacity, in the hope of obtaining evidence of the existence of displacement currents, but he had not been able to obtain any sensible effect.

Prof. AYRTON, referring to Prof. Thompson's experiment, pointed out that the greatest care was necessary in selecting the iron for such rings, and also in winding them, in order to obtain a perfectly inclosed field. He had made a number of experiments upon such rings, and found that they often possessed a series of poles, and when tested by means of iron filings were found to possess an external magnetic field.

Prof. FITZGERALD, referring to the same experiment, observed that it would be of great interest to investigate the effect of introducing substances of different specific inductive capacity into a field of varying vector potential. He pointed out that an *a priori* difficulty exists in the ways of observing these displacement currents so long as there is only a single medium present. In this case the displacement currents due to charging a simple point flow uniformly in all directions outwards from the point, and there are no experimental means of detecting the presence of such a system of currents. In the case of a number of points, the resultant currents will be the sum of those due to each, and therefore the same would hold good for any number of points distributed in any manner in space, so that if the medium were of exactly the same kind throughout, displacement currents could produce no magnetic effects, and, therefore, any such effects observed must be due to the currents which carry the charges to the points.

Prof. S. P. THOMPSON suggested that Dr. Lodge might get over the difficulty presented by the fact that all conductors are more or less magnetic by electrifying an absolute non-conductor by allowing an electric wind to play against it.

Prof. LODGE, in reply to Prof. FITZGERALD, stated that it would be very easy to calculate the momentum which was to be expected, and he had done so in a good many cases. The difficulty was to form an idea of the magnitude of the effect actually observed. An arrangement which might possibly give a sensible effect would be to bend an iron rod into a continuous rectangular circuit, wind a primary coil upon one side of the rectangle and a secondary upon the two adjacent sides; then suspend a hollow iron drum, with the unoccupied side of the rectangle placed in a vertical position coinciding with the axis of the drum; connect one terminal of the secondary to the iron core and the other to the iron drum by means of its suspension. If alternate currents were then sent through the primary coil the successive impulses might possibly give a slight rotation to the drum.

Prof. LODGE then read a Paper by himself and Dr. J. L. HOWARD

"On the Concentration of Electrical Radiation by Lenses."

In some of his recent experiments Prof. Lodge had found some difficulty in concentrating electrical radiation of considerable wave length. With waves only a foot or so in length he found that mirrors were quite sufficient. Prof. Hertz's experiments with a pitch prism suggested the use of lenses formed of that or some similar substance. Several substances were experimented upon, and ultimately the cheapest form of ordinary mineral pitch was employed, as it was found to insulate well, and it also had the advantage of possessing a high index of refraction. The lenses were cast in the form of hyperbolic cylinders bounded by a plane perpendicular to the axis of the principal hyperbolic sections. The eccentricity of these was 1·7, this being taken as an approximation to the refractive index of pitch for infinitely long waves. Such a lens should converge a bundle of parallel rays falling normally upon its plane surface to a focal line coinciding with the line of foci of its principal hyperbolic section. Similarly, rays proceeding from this focal line and falling on the curved surface should emerge from the lens as a bundle of parallel rays perpendicular to the plane surface. The plane surface of each lens was about 85 centimetres high and 90 centimetres broad, and the thickness through the vertex was 21 centimetres. They weighed about

Digitized by Google

3cwt. each. In making the experiment the lenses were placed with their plane surfaces opposed and parallel at a distance of 180 centimetres. The oscillator, which resembled a "Hertz oscillator" with some slight modifications, was placed along the focal line of one lens so that the electric rays proceeding from it would become sensibly parallel after traversing the first lens, and would therefore fall normally on the plane surface of the second one, and would be converged to its focal line. The distance from the oscillator to the vertex of the lens was 51 centimetres. This corresponded to about a wave length, which, calculated from the dimensions of the oscillator, was 100 centimetres, and according to interference observations similar to those described by Prof. Hertz, 102 centimetres. The direct effect of the oscillator upon the resonator was perceptible at a distance of 120 centimetres in the axial plane (viz., the vertical plane through the focal lines) of the two lenses in the most favourable case, that is to say, when the room was completely darkened and immediately after cleaning the knobs of the oscillator. Under similar circumstances resonance was only just perceptible at the upper edge of the first lens, which was at a distance of 85 centimetres from the oscillator. The resonator was found to give brilliant axial sparks near the first lens as long as it was held parallel to the oscillator; when it was rotated in a plane perpendicular to the axial plane the sparks were observed to decrease in brilliancy and length, and entirely disappeared when the resonator and oscillator were at right angles. When the rotation was continued the sparks reappeared and regained their former brilliancy after rotation through 180deg. When the resonator was placed in the axial plane, and then moved parallel to itself towards the edge of the lens, the sparks gradually decreased. The edges of the lenses on one side were close up to a brick wall about 40 centimetres thick, while on the other side was a passage about 54 centimetres wide between the lenses and the cupboards of apparatus. It was found that on the side nearer to the wall the sparks disappeared altogether at the edge of the lenses, but on the other side they were visible right up to the edge, and then ceased, after which the direct effect alone was obtained. The beginning of sparking as soon as the resonator entered the shadow of the lens was very marked. The radiation was always a little more visible on the side nearer to the wall than on the other side, which appeared to be due to some unexplained action of the wall. The radiation did not appear to undergo any sensible diminution in intensity through traversing the thickness of the lens. The concentration was very clearly shown by the fact that at the plane surface of the second lens, at a distance of 250 centimetres from the oscillator, the sparking was just as intense as the direct effect would be at 100 centimetres. The point of convergence of the rays beyond the second lens was fairly well defined, but the observers were unable to ascertain the existence of any sensible difference in the intensity of the sparking at its focus and at its surface. The intensity within the cone between the second lens and its focal line appeared to be very nearly equal in the neighbourhood of the axial plane, but the edge of the cone was slightly unsymmetrical on account of the disturbance on the side nearer to the wall. There was, however, no room for doubt as to the convergence of the rays to a focus. Beyond the focus of the second lens there were indications of a divergence of the cone of rays, specially noticeable just after the knobs of the oscillator had been cleaned. Some observations were also made after turning the oscillator through an angle, leaving its centre in the axial plane, its direction being inclined to this plane. The results obtained were of the same nature as those previously observed, but the intensity of the effects beyond the first lens were smaller. When the oscillator and resonator were parallel the sparking was always a maximum, and disappeared when they were at right angles. The results were throughout in complete agreement with those of Prof. Hertz.

DISCUSSION.

In the discussion which followed,

Prof. FITZGERALD pointed out that he had shown that the amount of energy radiated from a vibration is proportional to the fourth power of the rate of vibration, and therefore a comparatively large effect would be produced with a small oscillator. With a large oscillator a very small proportion of energy only would be radiated. Therefore, electricians need not be afraid of any serious loss of energy in alternating dynamos from this source. He stated that he had been very successful in using parabolic mirrors for concentrating the electrical radiations provided the knobs of the vibrator were properly cleaned. He would like to know whether Prof. Lodge had observed any alternations in intensity due to diffraction at the edge of the cone. He had been trying to obtain some results with electrical radiations analogous to Newton's rings in the case of luminous vibrations. There was no electrical reflection from a thin sheet of glass, showing an analogy to the black spot in Newton's rings. He had found that electrical rays falling upon a true non-conductor were invariably completely polarised. He was not at all surprised that Prof. Lodge had been unable to perceive any difference in the intensity of sparking at the focus and at the surface of the second lens respectively, for the Hertz resonators, though very effective as indicators, were very unsatisfactory for quantitative determinations, as even when differences in intensity were distinctly observable there were no means of deciding whether or not this was due to the knobs of the oscillator being in a more favourable condition. He found that the reflection from thick walls was somewhat better than from thin ones. He did not agree with Dr. Lodge that mirrors were less convenient than these lenses. He had used parabolic mirrors for concentrating radiations of considerable wave length, but it was necessary to use mirrors of a very large size.

Prof. LODGE, in reply to Prof. Fitzgerald, stated that he had never been able to perceive any fringes. Dr. Howard once thought that he saw them, but could not be at all certain. He remarked that probably his failure with mirrors was owing to their not being large enough, as the only ones he possessed were small.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, May 17th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 4, The Sanctuary, Westminster.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Optical Torque." By Prof. S. P. THOMPSON, B.A., D.Sc.

SATURDAY, May 18th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "The Origin and Development of Opera in England (with Musical Illustrations)." By JOSEPH BENNETT.

MONDAY, May 20th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture VI., 3. "Heat Engines other than Steam." By H. GRAHAM HARRIS, M.I.C.E.

TUESDAY, May 21st.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Some Recent Biological Discoveries." By Prof. E. RAY LANKESTER, M.A., F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Discussion on "The Treatment of Steel by Hydraulic Pressure, and the Plant Employed for the Purpose." By W. H. GREENWOOD, M.I.C.E. Time permitting, a Paper will be read on "West of India Portuguese Railway and Harbour Works," by ERNEST E. SAWYER, M.A., M.I.C.E. At this Meeting the last Ballot for Members for the present Session will be taken.

WEDNESDAY, May 22nd.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "The Use of Spirit as an Agent in Prime Movers." By A. F. YARROW.

THURSDAY, May 23rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Chemical Affinity." By Prof. DEWAR, M.A., F.R.S.

FINSBURY TECHNICAL COLLEGE.

7 p.m. Students' Conversazione. Lecture by Prof. SILVANUS P. THOMPSON, B.A., D.Sc., on "Arcs and Sparks."

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. "An Alternate Current Working." By W. M. MORDEY (Member).

FRIDAY, May 24th.

FINSBURY TECHNICAL COLLEGE.

7 p.m. Second Night of the Students' Conversazione.

INSTITUTION OF ELECTRICAL ENGINEERS.

9 p.m. Conversazione at the Royal Institute of Painters in Water-Colours.

ROYAL INSTITUTION

9 p.m. Evening Discourse. "The Solar Surface during the Last Ten Years." By the Rev. S. J. PERRY, D.Sc., F.R.S.

SATURDAY, May 25th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "The Origin and Development of Opera in England (with Musical Illustrations)." By JOSEPH BENNETT.

PHYSICAL SOCIETY.

3 p.m. 'On a Relation Existing Between the Density and Refractions of the Gaseous Elements and some of their Compounds." By the Rev. T. PELHAM DALE. "On a Water-spray Influence Machine." By GEORGE FULLER. Notes on Polarised Light:—(*a*) "On the Transition Tints of Various Orders." (*b*) "Lecture Illustrations of the Rotation of the Flame of Polarisation." (*c*) "On the Rotation of Circularly Polarised and Non-Polarised Light." By Prof. S. P. THOMPSON, D.Sc. "Terrestial Magnetism as modified by the Structure of the Earth's Crust." By Dr. EDMUND NAUMANN. "Molecular Weight of Caoutchouc and other Colloric Bodies." By Dr. J. H. GLADSTONE and Mr. W. HIBBERT.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," n order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

NOTICE.

Volume XXII. of "THE ELECTRICIAN," strongly bound in Cloth, is NOW READY. Price 12/6, post free, 13/6.

(The INDEX to Vol. XXII. was issued (Gratis) with "THE ELECTRICIAN" for May 10th.)

Cases for binding Volume XXII. are also NOW READY. Price 2/0, post free, 2/3.

Publishing Offices: 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
And at Manchester, Liverpool, and Glasgow.

SPECIAL NOTICE.

With this issue of "THE ELECTRICIAN" *is published a Steel Plate Portrait of the late* MR. C. H. B. PATEY, C.B., *Secretary for Postal Telegraphs.*

A limited number of copies have been mounted on India Paper, and for these early application must be made. Price 1/-, *post free,* 1/2.

The Portrait, in a neat frame, will be supplied at 4/6, *post free,* 5/-. *If mounted,* 5/6, *post free,* 6/-.

RAILWAY RATES AND THE ELECTRICAL TRADES.

THE Railway and Canal Traffic Act of last session, although not exactly what the Railway Companies desired or their customers demanded, was on the whole a satisfactory piece of legislation, and if administered by the Board of Trade, as we have every ground for believing it will be, in a spirit of fairness to both parties, the causes of dissatisfaction which have existed for many years past are likely to be almost entirely removed. A great deal will depend, however, upon the action of the trades affected by the Act; and it is gratifying to notice that the electrical interests have secured a powerful ally by affiliating themselves with the London Chamber of Commerce. The Report of the Committee of the Electrical Trades Section, just issued, and a copy of which will be found in another portion of this week's *Electrician*, sets forth some of the main points concerning which manufacturers of electrical machinery and plant are invited to express their opinion. More especially is their attention directed to the schedule of classified rates accompanying the Report, in order that any well-founded objections to them for local or special reasons by firms, either represented or not represented by the Chamber, may be embodied in the revision which the Electrical Section will endeavour to bring about.

Digitized by Google

No time should be lost in carefully examining the schedule and comparing the existing and proposed rates submitted by the Railway Companies for the approval of the Board of Trade. The Act came into operation at the commencement of the present year; and by the end of February the combined railways had their classified charges ready for inspection. The Act requires the companies to supply a copy to any applicant at a charge of one shilling, so that local firms ought by this time to be aware of any changes which are likely to affect them on the line of railway where they are situated. But the schedule above referred to will, it is thought, cover most of the ground so far as electrical plant is concerned; and for firms who may prefer to act independently an appeal direct to the Board of Trade is still open to them, the time for lodging objections having been extended until the 9th of next month.

The general character of the opposition to some of the proposed rates is briefly indicated in the Committee's Report; but it should be further borne in mind that this mode of correcting excessive charges on the part of a Railway Company is practically the only one available, any opposition in Parliament subsequently being in all probability of no use whatever. The Act provides that the companies shall submit their classified rates and terminal charges for a specified period during which they are open to objections from "all parties whom the Board of Trade consider entitled to be heard," suitable forms being provided under the Act and supplied on application to the Board, or they may also be obtained from the Chamber of Commerce. Obviously the grounds of objection must be not only reasonable but convincing; and the greatest care will have to be taken to so word the protest that the Board—or the Commissioners appointed under the Act—may be justified in deciding adversely to the Railway Company's proposals. The objections having been duly considered, and an agreement with the company arrived at, a Provisional Order embodying the classification so revised will be laid before Parliament in the usual way, and, if passed, will become part of the law of the land, against which there will be no appeal except by fresh legislation.

It is here that the Act of 1888 introduces a radical change in the relations of the Railway Companies with their customers. Attempts at legislating on railway rates have been continually made ever since railways were started; but until now it has always been possible to secure special privileges by mutual agreement, one well-known method being to remove the favoured article of commerce from one class to another for which lower rates prevailed. The rates were fixed, but the schedules were capable of manipulation. This will no longer be possible, the companies being bound by their classification to charge neither more nor less for the same or similar services than they are entitled under the Provisional Order. At first sight this hard and fast rule may seem disadvantageous to the customer; but one of the gravest complaints which has long been urged against the companies was that they granted preferential rates in their own interests often to the detriment of local industry, and always inimical to free and fair competition. It is believed that the present Act will do away with that injustice; and if it does so, lower rates ought to prevail all round; for it is evident that if the company allowed one class of goods to be carried at artifically low rates, other classes of goods were excessively taxed to make up the loss. Should any case of this kind be suspected under the operation of the new Act, the interposition of the Board of Trade can be invoked, and its decision as arbitrator will be final.

Another way in which the Railway Companies could impose rates which are technically described as "unreasonable" was in certain cases to increase the terminal charges—charges for loading and unloading, station charges, and charges for cartage. These were lumped together with the carriage rates, so that it was always possible to prove that the latter, if questioned, had not been exceeded, by increasing the balance due in respect to the other charges. These charges differ, of course, under differing circumstances, depending upon distance, speed, character of service, and so forth. Such reasonable variations are permissible under the recent Act, and are embodied in the classified lists now being considered; but under the Traffic Act of 1873 the only remedy against unfair usage in respect to terminal charges was by an expensive legal process, whereas the Act of 1888 provides summary process before the new Railway Commissioners who are created under the Act. The fact, however, that the companies are required, in the first instance, to define the nature as well as the amount of all terminal charges, will no doubt tend to obviate disputes of this kind in future. We have stated above that a classification cannot be altered, after it is approved by Parliament, without a fresh Act; but the Board of Trade has the power to add articles of merchandise omitted from the classification, and to class them at its discretion. This fact is of importance to electrical industry, as certain articles have been omitted from the list submitted by the Railway Companies; and it will be one of the first duties, among others, of the Electrical Section of the London Chamber of Commerce to see that they are inserted on "reasonable" terms.

THE CENTRAL STATION DISTRIBUTING MAINS AT BARMEN.

We are indebted to Messrs. W. F. Dennis and Co. for the following very interesting description of the method of laying the distributing mains in connection with the Barmen central station.

The year 1888 has witnessed the introduction of the electric light by central stations in a number of German towns, amongst which the town of Barmen is conspicuous, not only for the quality and soundness of the work done and for the arrangements, which are peculiar in many respects, but also on account of the special difficulties which the hilly character of the country presents to all underground work (there are steep hills on both sides of the River Wupper, with numerous crossings of that river and the "mill creek").

The general installation (buildings, steam engines, dynamos, accumulators, &c.), *see* Fig. 7, has been furnished by the firm of Spiecker and Co., of Cologne (which has in the meantime been amalgamated with the well-known firm of S. Schuckert, of Nuremberg). The cables have been manufactured and laid by the firm of Felten and Guilleaume, of Mülheim-on-Rhine.

The plant is for the first designed to furnish the current to 2,000 glow lamps of 16 candle-power each by means of two steam engines and four dynamos in combined action with 272 accumulator cells. The buildings are, however, so arranged as to admit of an extension to 6,000 lamps.

Having regard to the general disposition of the streets of the town, it was considered advisable to execute the cable system on the three-wire principle. It consists of—

a. The main cables or feeders carrying the current from the engine-house to conveniently situated points, at which it is divided by means of "main cable boxes." The positive and negative main cables are provided with one, the neutral cable with two, insulated tension wires enclosed under the same covering (*see* Figs. 1 and 2).

b. The distributing cables, which are connected to the beforementioned main cable boxes by means of lead cut-outs, and which at their crossings are connected among themselves by means of lead cut-outs in other boxes called "distributing cable boxes."

c. The house connection cables (*see* Figs. 3 and 4). Some of

Digitized by Google

these are connected by lead cut-outs direct to the cable boxes; the others ramify from the distributing cables.

The main cables, positive, negative, and neutral, are 36 in number, with sections of 190, 170, 120, 110, 90, 85, 60, 55 and

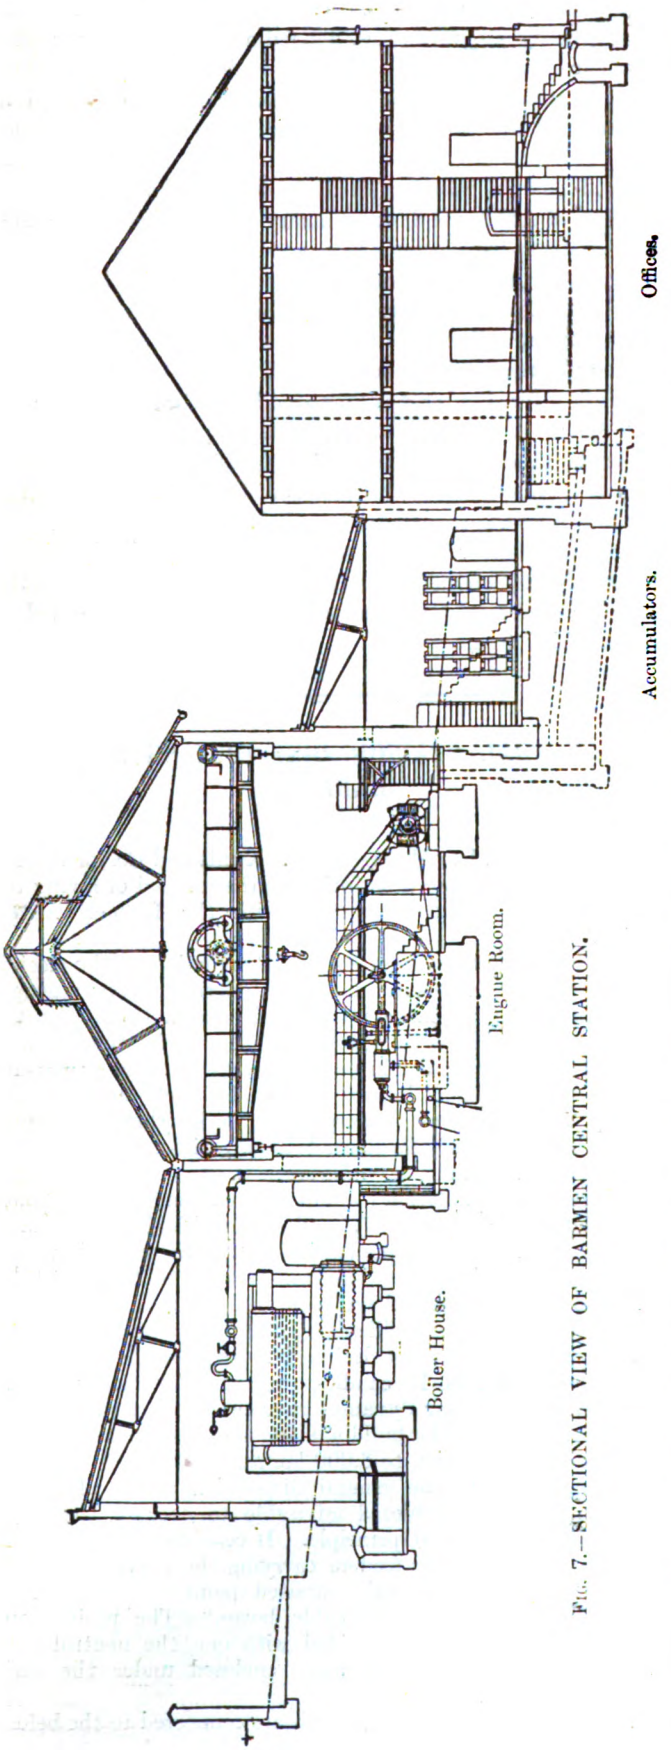

FIG. 7.—SECTIONAL VIEW OF BARMEN CENTRAL STATION.

50 square millimetres, forming a total length of 22,000 metres.

There are 204 distributing cables, with sections of 110, 80, 70, 50 40, and 30 square millimetres, forming a total length of 28,000 metres; and many kilometres of house-connection cables, with sections of 30, 20, 15, and 10 square millimetres.

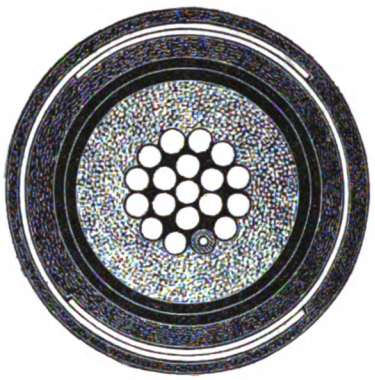

FIG. 1.

The total weight of all the cables employed is upwards of 200 tons.

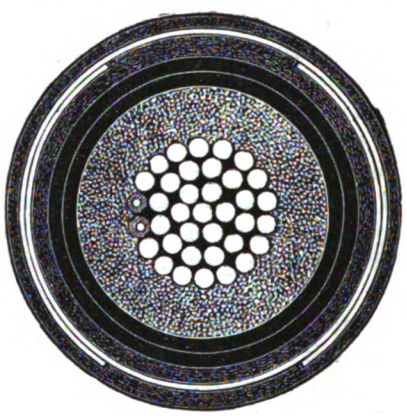

FIG. 2.

The longest distances of the system are :—

1,045 metres to east of engine-house,
1,250 „ west „ and
890 „ south „

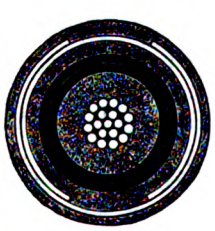

FIG. 3.

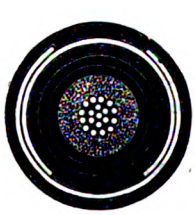

FIG. 4.

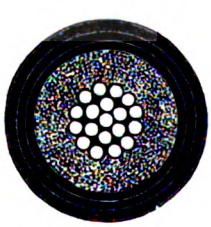

FIG. 6.

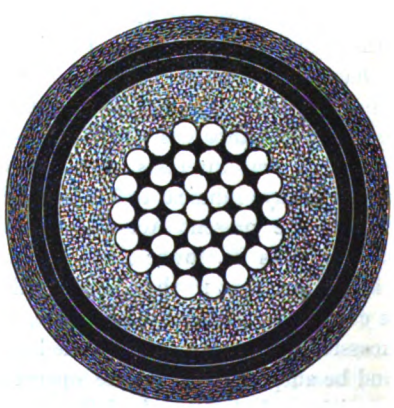

FIG. 5.

The cables are all carefully marked so as to be easily distinguishable in case of repairs later on. They are insulated

Digitized by Google

with Felten and Guilleaume's impregnated fibre, and provided with a double lead covering against moisture, as well as a double iron taping against mechanical damage. All cables have been tested under water in the factory at Mülheim-on-Rhine both with regard to conductivity and insulation resistance. They have also been kept under electrical control throughout the operation of laying. After completion the entire cable system, including all cable boxes and house connections, was tested from the central station by means of a delicate mirror galvanometer with very favourable results, exceeding by far the guaranteed figures.

For the purposes of distribution and equalisation of pressure there are in the system 41 cable boxes, viz., 12 main cable boxes and 29 distributing cable boxes. They have been specially constructed for the purpose by Messrs. Felten and Guilleaume according to latest improvements, and are interesting not only for the manner in which they are rendered watertight at the places where the cables enter, but also for the peculiar construction of the current-distributing circles. The brick foundations for the same are provided with a water sink-pit, and have to carry the manhole cover in the street plane. They are so arranged that at any time additional cables can be introduced without having to break up or to make alterations in the masonry.

The whole work of manufacturing and laying the cables took but a few months, while at the same time the firm of Felten and Guilleaume had to make and supply all the cables required for the central stations at Hamburg, Bremen, Lübeck, &c.

A description of the latter installations with regard to the general execution of the same by the firm of S. Schuckert, of Nuremberg, will be found in *The Electrician* of Feb. 8th, 1889. They are different from the Barmen installation in that they are constructed on the ordinary parallel system. Among the cables used in them there are sections of upwards of 600 square millimetres.

The total lengths of cable used in these various installations are as follows:—

Barmen	53,000 metres.
Hamburg	49,000 „
Bremen	21,000 „
Lübeck	21,000 „

All of these are lead covered, but in Hamburg, Bremen, and Lübeck the majority of the cables are not sheathed with ribbon iron (*see* Figs. 5 and 6), but laid in iron troughs with strong iron covers. Also in Hamburg the tension wires are not laid up in the main cables, separate small cables being used.

The experience gained by several years' use of Messrs. Felten and Guilleaume's impregnated fibre insulated and lead-covered cables speaks greatly in their favour. It may be mentioned that Messrs. Felten and Guilleaume also produce by the same process telephone as well as telegraph cables, both subterranean and aerial, of which a total of upwards of 1,500 kilo metres have left their works up to the present, and are in use in all parts of the world.

ELECTRICAL TRADES SECTION OF THE LONDON CHAMBER OF COMMERCE.

REPORT ON RAILWAY RATES.

The following is the report of the Sub-Committee on Railway Rates:—

To the Committee of the Electrical Trades Section of the London Chamber of Commerce.

Gentlemen,—We have carefully considered the provisions of the Railway and Canal Traffic Act, 1888, and have examined most of the proposed classifications of merchandise traffic and schedules of maximum rates and charges submitted to the Board of Trade by the various railway companies in pursuance of the provisions of the above Act. We have also carefully compared these proposed classifications, in so far as they affect goods with which the electrical industry is concerned, with the Railway Clearing House General Classification of goods at present in force; the schedule to this report contains a comparative statement of the existing and proposed classifications of such goods.

The proposed revised classifications were submitted by the railway companies to the Board of Trade in February last, and the Board of Trade have extended the time for receiving notices of objections till the 9th June next.

The category in which an article is placed determines the rate at which it is to be conveyed, and hitherto a revision of a rate was obtainable by a transfer of the article from one class to another. The classification to be made by the Board of Trade will, however, be permanent, and will be unalterable when once adopted by Parliament except by a new Act.

With certain exceptions the Companies in the revised schedules adopt the Clearing House classifications. The signs have, however, been varied:—

Class M (*a*) of Clearing House corresponds to Class A of Revised Classification.

Class M (*b*) of Clearing House corresponds to Class B of Revised Classification.

Class S (special class) of Clearing House corresponds to Class C of Revised Classification.

Class 1 of Clearing House corresponds to Class 1 of Revised Classification.

Class 2 of Clearing House corresponds to Class 2 of Revised Classification.

Class 3 of Clearing House corresponds to Class 3 of Revised Classification.

Class 4 of Clearing House corresponds to Class 4 of Revised Classification.

Class 5 of Clearing House corresponds to Class 5 of Revised Classification.

Classes A and B are not of special interest to the electrical trades.

The classification in Class C applies only to quantities of two tons or upwards; if goods in Class C are sent in consignments of less than two tons they are subject to the maximum and terminal charges in Class 1.

The rates in Classes 1 to 5 apply to quantities exceeding 560lb., an increase of 60lb. on the minimum usually fixed in the existing Acts.

Insomuch as all the railway companies whose proposed classifications we have examined have adopted a common classification, we do not think it necessary in the annexed comparative statement of existing and proposed classification to do more than mention one company—the London and North-Western Railway Company.

Upon reference to the annexed schedule it will be observed that the most serious variation in the proposed classification is the *entire omission* of the item "Dynamos and electric machinery," which, as the result of much effort, it will be remembered, was some time back transferred into Class 3 y when not packed, and Class 2 when in cases. The effect of this omission might be that electric machinery might be classed either under "machines fitted up or partly fitted up not otherwise provided for," not packed, Class 4; packed, Class 3; or under Class 5, the highest category, by being brought under the general definition of "all articles, matter and things not hereinbefore classified."

Although this is the most important objection to the proposed classification, which in our opinion should be strongly raised in the interest of the whole industry, there are no doubt several other modifications which can be shown to be unjust and unreasonable.

The classifications call for the most careful consideration of the various branches of the industry, but care should be taken not to multiply needlessly the objections to be raised. For instance, although "storage batteries" have been removed from Class 2 to Class 3, they can still be conveyed at Class 2 rates by being declared as "electric accumulators."

Other objections, again, as that to the placing of empties in Class 5, will no doubt be made by the Chamber on behalf of all trades.

There are a variety of other questions arising out of the provisions of the new Act, and of the proposed schedules of maximum rates and charges, and of the general conditions submitted by the railway companies, which merit the attention of manufacturers and traders in the country, *e.g.*, the general conditions which are proposed by the companies to govern the traffic, the question of terminal charges, the rates for small parcels, &c., but as these are not of special concern to the electrical industry, we recommend that the Electrical Trades Section should in these matters act in concert with the other Sections of the Chamber.

It would be well, however, for every member of the Electrical Trades Section to obtain the proposals of the railway company or railway companies of his district, and examine and report on such questions as the selection of "large towns" and "terminal stations," which have an important bearing upon the charges the companies will be entitled to make in respect of services before and after conveyance by rail.

[Members of the Section are requested to send in any additional facts interesting to the trade to the Secretary of the London Chamber of Commerce, Botolph House, Eastcheap, E.C.]

The Schedule will be found on next page.

Schedule of Existing and Proposed Classifications, in so far as they affect Goods appertaining to the Electrical Industry.

Description of Article.	Existing Classification.	Proposed Classification.
Acid, sulphuric	Under 2 tons in the carboys double 4	...
Accumulators, electric	2	2
Angle-plates, steel	For less than 2 tons, 1st	2 tons and up, C
,, ,,	Over, special	less 1
Asbestos	2	...
Bar iron	For less than 2 tons, 1	Less 1
	Over 2 tons, special	2 tons and up, C
Bar iron, puddled	10% over rates for pig iron	2 tons and up, C less 1
Bars, angle iron or steel	S	2 tons and up, C less 1
Bundles of bars—		
Under ⅜in.	1	1
Over ⅜in.	S	1
Capstan	1	1
Cast iron	1	1
Batteries, telegraph	3	...
,, electric storage	2	3
Bed plates, engine	S	2 tons and up, C less 1
Beds and cylinders	1	1
Belting, leather	3	3
Boiler fittings, except loco., and not accompanying the boiler	2	2
When with boiler at same rate as boiler.		
Boilers, less than 1 ton, occupying 1 waggon	2	2
Boilers under 30ft.	1	
,, above 30 and under 45ft	2	
,, above 45ft.	3	
Bolts and nuts, iron	S	2 tons and up, C less 1
Brass	2	2
Bronze (Phosphor) castings and ingot rough	2	2
Cable	4y	4
Carbons	3	3
Canvas belting	3	3
Carboys, not glass, empty, not returned	4	...
Ditto, glass, empty	3	...
Cardboard	1	3
Cardboard boxes, packed, except in cases	4	...
In cases	3	...
ars, Tramway	Miles. Per ton Per ton mile. added. Up to 20 ... -/3 ... 2/- 21 ,, 22 ... 7/- ton. 23 ,, 34 ... -/2¾ ... 2/- 35 ,, 38 ... 10/- ton. 39 ,, 40 ... -/2½ ... 2/- 41 ,, 54 ... 11/- ton. 55 & up. -/2 ton & 2/- add.	...
Chandeliers and gasaliers	5	5
Castings, brass	3	3
,, crank, unfinished	S	...
,, steel	37	2 and 3
,, rough and unfinished	1	1
,, iron, malleable	1	2
,, iron, light, packed	1	2 and 3
Cement	S	Blocks or slabs 4 tons up, B C, 2 tons up, less Class 1
,, and concrete	MB	,,
Cement and composition for retaining heat in boilers, in casks, cases, or bags	S	...
Cement, patent metallic	S	...
Chains, unpacked	S	2 tons and up, C less 1
,, packed	S	2
China, in boxes or cases	4	5
,, casks or crates	2	
,, hampers	3	
Cisterns, cast iron	2y	4
Cisterns and tanks, iron or wooden (not lined with lead)	2	4
Cisterns, wood and lead lined	3	4
Coal	MA	4 tons up, A 2 ,, C less 1
Copper	2	2
Cordage	2	2 ropes
Cotton waste	2	2
Cotton and linen goods in bales, boxes, cases, or trusses	3	3
Coupling boxes	S	...
Crucibles	3y	Clay 2, also 5 2 tons up, C less 1
Cullett	S	...
Delta metal	2	3
Disincrusting fluid	2	...
Dynamos and electric machinery, not packed	3y	...

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"On Lightning, Lightning Conductors, and Lightning Protectors."*

BY DR. OLIVER LODGE, F.R.S.

(Continued from page 9, Vol. XXII.)

SUMMARY OF POINTS OF DIFFERENCE AND CONTROVERSY.

39. In may be convenient here to summarise a few of the points wherein the doctrines which I advocate differ from the views held by the older electricians. And the summary will give me an opportunity of emphasising the incorrectness of the older views in many instances.

I quote a few statements prefixed by capital letters from an abstract I made for *The Electrician* after the Bath meeting of the British Association. (See *The Electrician*, September 21 and 28, 1888.)

A. Rods as at present constructed, though frequently successful, may and do sometimes fail, even though their earth is thoroughly good, the reason being that they offer to a flash a much greater obstruction—a much worse path—than is usually supposed—an obstruction to be reckoned in hundreds or thousands of ohms, even for a very thick copper rod. N.B.—This is not resistance proper, but impedance.

I may be permitted here to repudiate the doctrine which has several times been attributed to me since the Bath meeting, that it is safest to be without lightning conductors altogether. The long experience of persons learned in this art is by no means to be despised, and, until an agreement as to improvements has been arrived at, the safest plan for ordinary persons is to adhere to existing practice. Nevertheless, that conductors sometimes fail, is as certain as that they often succeed. My statement is that customary arrangements are not perfect and are susceptible of improvement. The statement of the Lightning-Rod Conference is that "there is no authentic case on record where a properly constructed conductor failed to do its duty." Mr. Preece calls the statement "most decisive." It is certainly *decided*, and in the light of other matter contained in the same red covers I assert it to be in its natural and intended signification decidedly false. The only signification which makes it true makes it also senseless, as if one should record the statement that white things are white. In my Society of Arts lectures I said nothing against the report of the Lightning-Rod Conference, because the work done by that body in collecting information, abstracting papers, and recording instances was obviously very valuable, and much of the report itself is correct; while as for the occasional rash statements in that document I imagined the signatories would wish them to sink into oblivion in silence. But Mr. Preece has revivified them, and conspicuously made himself afresh responsible for them;† accordingly I now extract one or two more sufficiently dogmatic and unfortunate statements from the same source.

"A man may with perfect impunity clasp a copper rod an inch in diameter, the bottom of which is well connected with moist earth, while the top of it receives a violent flash of lightning." "If all these conditions be fulfilled; if the point be high enough to be the most salient feature of the building—no matter from what direction the storm may come—be of ample dimensions, and in thoroughly perfect electrical connection with the earth, the edifice with all it contains will be safe, and the conductor might even be surrounded by gunpowder in the heaviest storm without risk or danger." To adhere to such views as these now, with tenacity sufficient to cause them to be promulgated as authoritative scientific statements, would be, in my opinion, little less than criminal.

"All accidents may be said to be due to a neglect of these simple ele mentary principles." Certainly this "*may be said*," because it already has been said over and over again; but it cannot be said with truth.

Whenever an accident happens, a believer in the modern exponents of the Lightning-Rod Conference who could not point out a flaw, or a bad joint, or a bad earth, or a possible flaw, or a possible bad joint, or a possible bad earth, would feel himself disgraced as a practical man. An instance occurred in quite a recent number of *Nature*. The writer of "Electrical Notes" records that a number of fish had been killed in a pond into which the earth end of a conductor had been led, and concludes with the ejaculation, "When will people learn to make proper earth connections?" I select this instance as typical of the extraordinarily contradictory advice often bestowed on that long-suffering body the British

* Paper read before the Institution of Electrical Engineers on Thursday April 25, 1889.

† Saying at Bath, as a prelude to a quotation from the report, "The report itself is most decisive and most important; there is a true ring about it—the ring of men who knew what they had done and what they were writing about."

Digitized by Google

public. Before an accident, the pond would be pointed out as an excellent earth, as indeed it most likely was. After the slaughter of the fish, the erector of conductor is impersonally ridiculed for having utilised it. So with any struck building. After an accident defects *must* be forthcoming, because else there would be "an authentic case on record where a properly-constructed conductor failed to do its duty," which *ex hypothesi* is absurd and impossible; therefore it was not constructed in accordance with the directions of the Lightning Rod Conference therefore it was defective. Q.E.D.

B. When a Leyden jar is charged it corresponds to a bent spring, and its discharge corresponds to the release of the spring. Its discharge current alternates, therefore, in the same way and for much the same reason as a twitched reed or tuning-fork vibrates. The vibrations decay in either case because of frictional heat production and because of the emission of waves into the surrounding medium. A single spark of a Leyden jar, examined in an exceedingly fast revolving mirror, is visibly drawn out into a close succession of oppositely-directed discharges, although its whole duration is so excessively minute.

It is very likely that this statement will now no longer be denied. So I pass to the next.

C. A lightning flash is a spark between cloud and earth, which are two oppositely electrified flat surfaces, and the flash corresponds therefore to the internal sparking between the two plates of a great air condenser. All the conditions which apply to a Leyden jar under these circumstances are liable to be true for lightning. Sometimes the resistance met with, either in the cloud itself or in the discharger, may be so great that the spark ceases to be oscillatory, and degenerates into a fizz or rapid leak; but there can be no guarantee that it shall always take this easily manageable form; and it is necessary in erecting protectors to be prepared for the worst and most dangerous form of sudden discharge. The apparent duration of a lightning flash is due to its frequently multiple character, and indicates successive discharges, not one long-drawn-out one. Nothing that lightning has been found to do disproves its oscillatory character, because Leyden jar discharges, which are certainly oscillatory, can do precisely the same.

This was in answer to Mr. Preece's contention that lightning could not be oscillatory, because it magnetised steel bars and deflected ships' compasses. The next is an antidote to the continually made statement that the one thing needful for an efficient lightning conductor is *conductivity*.

D. Although some conductivity is necessary for a lightning conductor, its amount is of far less consequence than might be expected. The obstruction met with by an alternating or rapidly varying discharge depends much more on electro-magnetic inertia or self-induction than upon common resistance. So much obstruction is due to this inertia that a trifle more or less of frictional resistance in addition matters practically not at all. It is very desirable to have a good and deep earth in order to protect foundations and gas and water mains from damage, and in order to keep total impedance as low as possible.

I find it sometimes thought that I have argued against the need of a good earth. This is not so. I have argued against the exclusive and exaggerated attention that has been paid to this need.

In opposition to the following statements, *e*, *f*, *g*, *h*, *i*, the substance of which may be considered as hitherto orthodox, I make the statements subsequent, labelled *E*, *F*, *G*, *H*, *I*:—

e. No danger is to be feared from a lightning conductor if only it be well earthed and be sufficiently massive not to be melted by a discharge. All masses of metal should be connected to it, that they may be electrically drained to earth.

f. The shape of the sectional area of a conductor is quite immaterial; its carrying power has nothing to do with the extent of surface; nothing matters in the rod itself but sectional area or weight per foot run, and conductivity.

g. Points, if sharp, should constitute so great a protection that violent flashes to them ought never to occur.

h. Lightning conductors, if frequently tested for continuity and low resistance by ordinary galvanic currents, are bound to carry off any charge likely to strike them, and are absolutely to be depended upon. The *easiest* path protects all other possible paths.

i. A certain space contiguous to a lightning rod is completely protected by it, so that if the rod be raised high enough a building in this protected region is perfectly safe.

These statements I say are erroneous. The following I believe to be correct:—

E. The obstruction offered by a lightning rod to a discharge being so great, and the current passing through it at the instant of a flash being enormous, a very high difference of potential exists between every point of the conductor and the earth, however well the two are connected; hence the neighbourhood of a lightning conductor is always dangerous during a storm, and great circumspection must be exercised as to what metallic conductors are wittingly or unwittingly brought near or into contact with it. When a building is struck, the oscillations and surgings all through its neighbourhood are so violent that every piece of metal is liable to give off sparks, and gas may be lighted even in neighbouring houses. If one end of a rain-water gutter is attached to a struck lightning conductor, the other end is almost certain to spit off a long spark, unless it also is metallically connected. Electric charges splash about in a struck mass of metal as does the sea during an earthquake or when a mountain-top drops into it.* Even a small spark near combustible substances is to be dreaded.

F. The electrical disturbance is conveyed to a conductor through the ether or space surrounding it; expressed more simply, lightning currents make use of the periphery of a conductor only, and so the more surface it exposes the better. Better than a single rod or tape is a number of separate lengths of wire, each thick enough not to be easily melted and well separated so as not to interfere with each other by mutual induction.

The liability of rods to be melted by a flash can be easily overestimated. A rod usually fails by reason of its inertia-like obstruction and consequent inability to carry off the charge without spittings and side flashes; it very seldom fails by reason of being melted. In cases where a thin wire has got melted, the energy has been largely dissipated in the effort and it has acted as an efficient protector, though, of course, for that time only. Large sectional area offers very little advantage over moderately small sectional area, such as No. 5 B.W.G.

G. Points, if numerous enough, serve a very useful purpose in neutralising the charge of a thunder-cloud hovering over them, and thus often prevent a flash; but there are occasions easily imitated in the laboratory, when they are of no avail—for instance, when one upper cloud sparks into a lower one, which then suddenly overflows to earth. In the case of these sudden rushes, there is no time for a path to be prepared by induction, no time for points to exert any protective influence, and points then get struck by a violent flash just as if they were knobs. Discharges of this kind are the only ones likely to occur during a violent shower, because all leisurely effects would be neutralised by the rain drops better than by an infinitude of points.

H. The path chosen by a galvanic current is no secure indication of the course which will be taken by a lightning flash. The course of a trickle down a hill side does not determine the path of an avalanche. Lightning will not select the easiest path alone; it can distribute itself among any number of possible paths and can make paths for itself. Ordinary testing of conductors is therefore no guarantee of safety, and may be misleading. At the same time it is quite right to have some system of testing and of inspection, else rust and building alterations may render any protector useless.

I. There is no space near a rod which can be definitely styled an area of protection, for it is possible to receive violent sparks or shocks from the conductor itself, not to speak of the innumerable secondary discharges which by reason of electro-kinetic momentum and induction, by reason of electro-magnetic waves, and of the curious recently-discovered effect of the ultra-violet light of a spark, are liable to occur as secondary effects in the wake of the main flash.

Instructive Extracts from Reports of Damage by Lightning.

40. Reading between the lines of existing reports on damage done, one can frequently find evidence of many of the phenomena to which I have now called attention. Of course they are not recorded in any prominent manner, because they are to the observers ill-understood and puzzling facts; it is very difficult to note what has exactly happened in any given case unless some clue or expectation has been formed beforehand. The bad conductivity clue, which was the only one prominently available to the skilled recorders in the following cases, is a very partial one, and in many cases is quite insufficient to account for the facts without undue pressure being put upon it.

Under such circumstances the record of the facts is, of course, far more valuable than the comments made upon that record; and in the following extracts the theoretical remarks should be eliminated or slurred over.

One minor imperfection, common to many accounts, is that they are not sufficiently alive to the possibility of all manner of branching discharges, so that the discharge is said to leave a conductor and go to something else, when the truer statement would be that some *portion* of it branched off at such and such a point.

In the following quotations the references are usually to the pages of the volume of the Lightning-rod Conference, published by Spon in 1882:—

41. Illustrating Side Flashes and Surging Circuits.

"*L.R.C.*, p. 39.—*J. Murgatroyd. St. Mary's, Crumpsall, near Manchester.*—A lightning conductor from spire touched the eaves gutter, and a gas pipe touched the end of this gutter. The lightning passed from the conductor along the gutter to the gas pipe, melted it, and set the church on fire by igniting the gas."

"*L.R.C.*, p. 39.—*Wyatt Papworth.*—Tall spire struck. The church stands in an open position with no large trees near. It was

* *See* the Report of the Krakatoa Committee.

Digitized by Google

provided with an iron lightning conductor ¾in. diam., fixed with iron holdfasts and carried down inside the spire and tower into ground; the top of it was said to be attached to a bold copper finial on the spire about 150ft. from the ground and 50ft. above ridge of roof; the lightning is supposed to have first struck the finial, it slightly deranged some beds of masonry in upper part of spire, then descended by iron rod to belfry, melted a gas tube in the floor, and set fire to the belfry by igniting the gas."

From Abstract of Report on the Destruction by Lightning of a Gun powder Store at Bruntcliffe, Yorkshire. By Major V. D. Majendie, R.A. (L.R.C., p. 77.)

"The gunpowder exploded at 4:30 p.m. on August 6, 1878, during the greatest intensity of a violent thunderstorm. The building was brick, with brick arched roof, length 9f.t, with 5ft., height 6ft. (internal dimensions). The store had a uniform thickness of three bricks, and was furnished at one end with an iron door, at the other end with a lightning conductor. The conductor consisted of a copper wire rope, 10 gauge copper wire, the rope being $\frac{7}{16}$in. thick, having four points at the top (one large one in the centre, and three smaller ones round it); it extended to about 13ft. above the top of the building, and about the same length was carried into the ground and terminated in a drain. The conductor had been erected in 1876 by Mr. John Bisby, of Leeds, and was fixed to a pole distant about two inches from the end of the building opposite to that in which the iron door was fixed (it was not connected with the iron door in any way). No one was near the store when the powder exploded, and it seems probable that [the earth connection of the conductor was bad, that] the mass of iron in the door offered at least an equally good path—and that the gunpowder was ignited by a flash passing between the two imperfect conductors."

To make this report completely scientific, it would be well to omit the words I have put in square brackets.

Extract from a reply of Mr. Baldwin Latham, C.E.:—

"It is no uncommon thing for buildings provided with what are called lightning conductors to be damaged by lightning, and the cause is due to the inadequacy of the conductor to carry the electric fluid, which will leave the conductor for a better or a larger conductor." (*See* also Sec. 43.)

42. As illustrating that a good conductor affords no absolute security, the following document is worthy of reproduction in full, as given in *L.R.C.*, p. 115:—

"*Ueber Blitzableiter und Blitzschläge in Gebäude welche mit Blitzableitern versehen waren. Von G. Karsten. Keil. 8vo. 1887. (Abstracted by R. Van der Broek.)*

"In this pamphlet Dr. Karsten gives an account of two cases in which buildings that were provided with lightning conductors were damaged by lightning. The author states that the statistics for the year 1873 show that in Schleswig-Holstein twenty-six per cent. of all the cases of fire were caused by lightning; $\frac{1}{130}$ part of these cases occurred in the towns and the remainder in the country.

"Do lightning conductors guarantee absolute protection? The author answers this question as follows:—There is no absolute certainty in empirical matters; each new case may direct our attention to circumstances that had been overlooked. If lightning conductors cannot be said to ensure perfect safety, they certainly afford a very high degree of protection.

"The flash of lightning which struck the church at Garding, on the 18th of May, 1877, fractured the conductor in fifteen places, and pierced the wall of the steeple in two places. The inefficiency of the conductor resulted from the carelessness with which it was fixed; the line was laid down the north side of the steeple and fastened with 25 wall eyes; these wall eyes were hammered too deep into the wall, thus damaging the line and forming a short and sharp bend in each case, besides also unduly straining the wire. The damage to the steeple was the consequence of a neglected secondary circuit. There are an excessively large number of tie-rods in the steeple; the heads of these rods are not connected together, neither are they, except in one case, in close proximity to any of the larger masses of metal that are about the building. The conductor passed close to one of those heads; the south side of the steeple, where the opposite head is, becoming wet through the rain, a secondary circuit was formed, and a return shock followed; the damage to the steeple was trifling.

"The rod was provided with a conical point, rather blunt, but surmounted by a short platinum point. The copper line-wire was of good material—not of a uniform thickness, but at the weakest places not weighing less than 240 grammes per lineal metre (8oz. per yard, or rather less than ¼in. diameter if solid). The earth-plate was sunk into a well 10 metres deep, and tested faultless after the discharge."

43. The following series of notes are better not separated, though they bear upon different points:—

L.R.C., p. *93 et seq.—From Abstract of Statistics of Buildings and Ships struck by Lightning. By F. Duprez, Member of the Academy.*

Illustrating occult dangers from secondary disturbances in the neighbourhood of conductors.

"The author cites three cases of buildings set on fire though protected by lightning rods. But the precise cause of the fire was not ascertained."

Illustrating multiple flashes.

"In each of two cases the lightning struck at once the three rods fixed to a building."

Illustrating that a poor earth is not necessarily fatal to the efficiency of the conductor, except as to the protection of the soil itself and of things buried in it.

"Out of fifteen cases of lightning rods struck, in which the conductors were simply buried more or less in the soil, they carried off the strokes in eleven without the buildings being injured or any trace being left of it, except that the ground was upheaved where the latter was too dry."

Illustrating a matter important, if true: suggested by Prof. Fitzgerald theoretically at Bath: not yet verified by me.

"In two cases the stroke broke the conductor at points where its direction was abruptly changed."

Illustrating side-flash.

"In two other cases the lightning left the conductors struck, and fell upon buildings near, without causing damage to those on which the rods were fixed."

Illustrating brush discharge from conductor, and surging circuits its neighbourhood.

"Two electrical phenomena are to be noted as sometimes occurring when a lightning rod is struck. First, when a conductor is formed of metallic plates a peculiar noise is heard like water pouring on a fire. Second (independently of the form of the conductor), electric sparks are emitted from bodies near. The author cites examples at Berne, 1815."

44. The following illustrate the carrying power of fairly thin wire, and the fact that thin wires may protect although themselves deflagrated. *From Mr. Preece's Paper on "Lightning" to Society of Telegraph-Engineers, November*, 1872 (*L.R.C.*, p. 101):—"There were only two cases in the past season where line wires (No. 8 iron 0·17in. diam.) were absolutely fused.

From letter by Admiral Sullivan (*L.R.C.*, p. 195):—"You will like to know a case in which a copper wire acted as a perfect conductor, *though fused throughout its length*. It was at Monte Video, in the house of the English Consul; a flagstaff was struck and conducted the lightning through a flat roof near the bell wire of a suite of rooms (the wire ran in sight near the cornice) through a hole in each dividing wall, and then down to the bell in the basement. The wire was melted into drops like shot, which burnt a row of small holes in the carpet of each room. A dark mark on the cornice above showed where the wire had been. At the bell there was a slight explosion and some little damage, but I do not recollect whether anything acted partially as a conductor from that point and so carried off that part of the charge.

"This, I think, shows that even an ordinary bell wire will act as a conductor for a rather strong stroke of lightning, as the large flagstaff was shattered."

45. As illustrating that experience has led to the perception of the value of large surface to a rod, I may quote the standard American work, Spang's "Practical Treatise on Lightning Conductors." Philadelphia, 1887 (*L.R.C.*, p. 113):—

"A conductor of large surface exercises a much greater protective action than the same quality of metal in the form of a wire or solid rod.

"Not because electricity in motion resides on the surface, but that the expansive action of a discharge may have a wider scope through the metal."

[The incoherence of the reason does not destroy the correctness of the stated fact.]

Messrs. D. Munson and Co., of Indianapolis, Indiana, have sent me specimens of their rods, which have flanges and sharp edges, and in various ways aim at large surface. Their rods are composed of copper and iron mixed, which is curious, and their mode of attainment of large surface is needlessly complex.

The following illustrates the contradictory views about manner of conduction by lightning rods. *Letter from Admiral Sullivan* (*L.R.C.*, p. 199):—

"I firmly believe in the surface theory of Harris. I had been with him often when he made experiments nearly fifty years since, and witnessed a strip of tinfoil of the thinnest kind, and about ½ inch wide, protect a model mast of about six inches in diameter from electric shock, that without it split the mast to pieces, aided by a small hole through its centre filled with gunpower. And I

Digitized by Google

always thought that the surface-conducting theory of Harris was indisputable. But about 20 years since, having to approve a proposal of the Trinity House for a new conductor of a lighthouse, which, like previous ones, was an inch in diameter copper rod called 'Faraday's Plan,' I thought I would go up to the Royal Institution and ask him why he did not use a copper tube instead, giving much greater conducting power with less copper. I did so, and he asserted positively that the conducting power depended entirely on the volume of copper in the section of the conductor, no matter whether it was in a bolt, plates, or tube ; and that if Harris said differently, 'he knows nothing whatever about it.' Of course I approved the rod-conductor ; but singularly enough, though I had not seen Harris for years, he came to town a few days after, and came to the Board of Trade to see me, and bring me a piece of his large tube conductor, with a connection that he was fitting to the Houses of Parliament. When I told him what Faraday's opinion was, he answered, 'Then he knows nothing about it.'"

(To be continued.)

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 27, 1889.*

The prevailing sensation in electrical circles continues to be the cutting down of the poles and wires by the Subway Board. Up to the present time of writing the city Bureau of Encumbrances, acting under the instructions of the Board, has removed about 100 to 125 poles and some 300,000ft. of wire, and would have removed more but for the fact that the companies have sent their men along the line in advance of the official gangs, and have themselves dismantled the poles. I need hardly say that this work has greatly interrupted electrical business of all kinds, and more particularly that of the electric light companies, although the main object of the crusade ostensibly has been to compel the Western Union Company to acknowledge the Board's authority. This week a fine line of poles on 42nd-street, 75-foot Norway pines, the property of the Metropolitan Company, were cleared away. Although the poles are not perhaps the most æsthetic objects we are wont to look upon, there are many among us who have a feeling of regret at seeing them disappear. The streets are undoubtedly a great deal more sightly than they were before the crusade began, but the question is now agitating electricians here as to the effect on all the electrical services. It is feared that they will be crippled in more than one way, for even if the subways proved equal to their work, the prices charged for operating in them are so high, it is claimed, as to place some of the services beyond the range of commercial possibility. In other words, it will not pay to operate under such conditions. Of course this remains to be proved, but I fear there is something in it. Another bad episode is the effect that is being had upon other communities. Thus, in Philadelphia the forcible removal of the telegraph and other poles and wires by the authorities has created a revived interest in the subject on the part of the city council, and we are likely to see similar work begun there, although Mr. Walker, the city electrician, says that only the Legislature can grant the necessary authority to abolish the overhead wires, and that it would take five years to provide the proper underground conduits. We must naturally expect, however, to see the underground work in such large cities as New York and Philadelphia, but the reform or improvement is reduced to an absurdity when it comes down to little places of ten or twelve thousand inhabitants, where the trim and well-kept poles are certainly not among the eyesores along the streets. For such communities to want underground wires is the height of folly, and it may be gravely doubted whether they do want them, although the local papers now and then say that such wires are demanded. It begins to look as though practical electricity would undergo a pretty severe ordeal in this country as the result of this work in New York, but we are fain to believe that it must lead us to better things of one kind or another.

The Westinghouse Electric Light Company report doing a very large amount of business with the alternating system. They state that during the first half of the present month they have received orders for alternating current outfits aggregating a capacity of 10,750 lights, which figures out a neat rate for the year if it were maintained. A year ago 79 central stations were using or erecting Westinghouse alternating plant, but at the present time the number has reached 160, with an aggregate capacity of 300,000 16 candle-power lamps. When it is remembered that the Thomson-Houston and Fort Wayne Jenney Companies are also in the field, busily engaged selling alternating current apparatus, it will be seen that the system has obtained good foothold in this country, and bids fair to maintain its position as an important factor in the electric lighting business. With regard to the Fort Wayne Company, it is to be noted that the Westinghouse Company has just brought an action against it for infringement of a patent granted to the United States Company, which it controls, on laminated cores for the armatures of dynamos. This patent was applied for in 1882 by Mr. Edward Weston, who was then connected with the United States Company, and was at last taken out a few days ago. It is quite a broad patent, covering "a core for electrical generators operating by inductive action composed of alternate sections, plates or discs of magnetic and insulating materials in combination with insulated coils wound thereon." Such a patent, if sustainable, is worth fighting for, and the suit just referred to is an indication that we are to have some more of the electrical litigation which has proved such a gold mine to the lawyers for years and years past.

The boom that I recently predicted in electric railways is now upon us, and construction work is now going on actively in every section of the country. Two electric railroads are being put in in Cincinnati, each of the overhead system, one using rail return, and the other complete overhead metallic circuit. At Topeka, Kan., the finest electrical railway in the West is now in operation, being 14 miles long, and having 20 miles of track. It will run 30 or 40 cars, and operates on the Thomson-Houston system. At Salt Lake City the Sprague Company have just received a contract for an overhead system, starting with 10 cars. They have also received another contract for a road to be put in at Portland, Oregon. These contracts involve the expenditure of very large sums of money, and the fact that so much is being invested in plant of this character shows how strong is the faith now felt by shrewd business men everywhere in the entire practicability of electric railways.

Mr. P. B. Delany whose synchronous multiplex system is said to be employed in your postal telegraph service, has brought out an improvement on the old Morse system which seems to add considerably to its value, especially in bad weather. Probably your readers, not being quite as familiar with the closed circuit Morse system employed in this country as with the open circuit and reverse current employed abroad principally, may find it strange to be told that frequently, with leaky lines, way or intermediate offices find it impossible to secure communication with terminal offices, and *vice versa*. This trouble is owing to the fact that the leaks on the line shunt sufficient current to cause the termiual operator's own relay to respond, and to make him think that all others on the line are receiving his signals, whereas those at way stations, not having their relays in adjustment, may be entirely unaware of any signals passing over the line. For this reason, therefore, being unconscious that the line is in use, say, between terminal stations (whose relays are always kept well adjusted), the way operators continually "break in," and thus make the line totally useless for communication. Of course this would not be the case if the reverse current were used with polarised relays, but as the Morse system is almost exclusively employed in this country, and frequently from 30 to 50 offices are placed on one line, especially in railroad work, some means of obviating this difficulty becomes of importance. Without going into the details of the methods employed by Mr. Delany, which, by the way, are very simple, I may state that the object is accomplished by causing two breaks to occur simultaneously at each end of the line whenever the key is depressed. It follows from this that no matter what the adjustment of any intermediate relay, with two absolute breaks in the line, however leaky the wire, the current is bound to be interrupted, and hence even badly adjusted intermediate relays will respond. The apparatus employed consists merely of an auxiliary trailer arrangement similar to that employed in Mr. Delany's recent system of cable transmission, which breaks the line at both ends for an instant at each contact of the key. I am told that the apparatus has been at work for some months on a number of railroads, and has given great satisfaction.

NEW YORK, *May* 4, 1889.

Electric railways have now been in operation in this country for some time in what may be called a practical shape, *i.e.*, in such a condition that their results should offer us some information or guidance as to their relative efficiency and economy. A great many estimates and statements have been made, but up to the present time we have had little in the shape of definite data. This lack now promises to be supplied very speedily, and there is every reason to believe that the publication of the figures will, if anything, increase the favour with which electrical locomotion is viewed rather than detract from it. Thus, for example, the president of the Sprague Electric Railway, which has been in operation for some months at Davenport, Indiana, comes forward with some very interesting comparative figures, and he naturally expresses himself as well pleased. This road, by the way, began with a good deal of confidence in electricity, for its

* This letter arrived too late for our last issue.—ED. *E.*

Digitized by Google

horses were advertised for sale, if I am not mistaken, even before the electric motors had actually got down to their work. The company have been fully justified, however, on their own showing. The road now has four 14-foot cars in operation, each equipped with two 7½ horse-power motors, and it has also one 10-foot car for transfers. It appears that in December of 1887, with horses, the gross receipts were $1,283, and the net $353, whereas, with electricity, the gross receipts were $2,022, and the net $1,120. This shows an increase in the gross receipts of 59 per cent., and an increase in the net earnings of 220 per cent. I believe that these figures can be matched on various other roads, but, of course, as can be readily understood, a great deal depends both on the skill in management and on the cost of fuel. It has already been discovered that a careless superintendent can run his road into a ruinous condition in a very few months, while a careful one will have the cars in better condition a year after operation than when he began. What may be said of the superintendent may also be said of the drivers or "motorneers," as it is unfortunately becoming the fashion to call them. But it is remarkable how quickly the men, hitherto unaccustomed to handling machinery of any kind whatsoever, become familiar with the manipulation of the electric motors, a feature which augurs well for the general introduction of motors in every class of industry. Returning to the question of fuel, it may be pointed out that some of the roads have already utilised water-power with great success, but in other cases it has been found that coal was even cheaper than water. In other words, the power stations are simply burning up the heaps of culm, or coal dust, which have been accumulating for forty or fifty years, and which in some places, as at Scranton, are of prodigious extent. This culm can be had at a cost of something like 10 cents a ton, so that the station can afford to burn a good deal of it and yet not be worried as to the expenditure on its coal bill.

While I am speaking of electrical transportation, I may call attention to a new system which has been introduced recently by Mr. J. F. Williams, and is now being exploited by the Port Electric Company of this city. This system is based on the sucking action that a helix or coil exerts on a rod of iron placed near its centre, so that if the bar be placed with one end in the hollow of the helix, it will be drawn in on the passage of the current, and will be maintained in a central position as long as the current continues. If the current be broken the bar will again be free to move, and if we suppose the second helix to be placed in a line just beyond the first, then on the passage of the current through the second coil the bar will be drawn towards that and out of the first. Thus, with a number of helices arranged in a line side by side, with an arrangement for making and breaking the current at the proper time, the bar of iron can be moved continuously in any given direction. This is the idea upon which Mr. Williams has based his system, which he proposes to utilise for the transportation of small packages and letters. The experimental apparatus has been on exhibition in this city for some little time past, and has, I understand, created quite a favourable impression. In the model a road is shown which is intended to carry a small car for the transportation of medium-sized packages, &c. This car is in the shape of a long flat box, built of light steel, and rests upon a single rail, being guided by a small upper rail and two upper flange-wheels. The coils of wire are raised on a simple iron lattice-work, with a single support, and are covered in and protected from the weather. The track constitutes one side of the circuit, which passes through each helix by a contact point, and then to the other side of the main conductor. As soon as the circuit is closed through the helix the car is drawn in with a sucking action. This contact is maintained at each helix up to the time that the centre carriage runs to within a short distance from the centre of the helix, when the magnet which makes contact becomes neutralised and the contact is broken, throwing the current into the next helix; and this action goes on indefinitely, each helix coming into action successively. The current is thus utilised to the best advantage, and it will be readily understood that when once the carriage is in motion through the semi-tube, and its inertia has been overcome, comparatively little current will be necessary to maintain it at speed. As a consequence the strength of the current can be considerably diminished a short distance from the starting station, as the power required is decreased greatly when the carriage is run at its proper speed. It is also interesting to note that the current in the helix is considerably cut down by the counter E.M.F. generated by the passage of the carriage through them, so that, in a sense, the system is self-regulating to maintain the carriage at its proper speed. This system has been provided with a brake in the form of a helix, similar to the others, but provided with a contact that, unlike the others, remains closed after the carriage has passed the centre. The effect of this is that the car is retarded or pulled back, and it is remarkable how quickly this brake brings the car to a standstill.

There has been little business of any kind done in New York this past week, owing to the fact that Monday, Tuesday and Wednesday were given up wholly to the celebration of the centenary of the inauguration of Washington as the first President of the United States. The ceremony performed a hundred years ago took place in this city, then a little place of about 30,000 to 40,000 people, and it has now been celebrated with all possible enthusiasm, expenditure and *eclat*. One great feature was the industrial parade on the third day, in which at least 50,000 people actively participated. Although the electrical trades were not among those represented in the line, they were nevertheless brought forcibly to the public attention by means of the electric motors with which some of the machines on the huge trucks were driven. These motors were furnished with current from small sets of storage batteries, and were placed conspicuously so that millions of the spectators could readily see how easily and noiselessly they do their work. One of them was running a miniature chocolate factory, and another drove a neat little printing office. Another striking exhibit of the same class was that of a full-sized Thomson-Houston electric car built by John Stephenson, and intended to run on one of the roads in Brooklyn. It was a very handsome piece of work, and was probably the first electric car seen by many hundreds and thousands of the spectators.

You will remember that some time ago I made note of the intention to bring all the parent Edison companies into one big combination or corporation. For a time little has been heard about the matter, and in some quarters it has been rumoured that the programme would not be carried out. This, however, is wrong, and the certificate of the incorporation of the Edison General Electric Company has now been filed in this State; while $15,000, the State tax of ⅛ of one per cent. on the capital stock of $12,000,000, has been paid into the State Treasury It will be remembered that Mr. Henry Villard, once the controlling spirit of the Northen Pacific Railroad, is prominently connected with this stupendous scheme of reconstruction.

Dr. S. S. Wheeler, the electrical expert of the Subway Board, recently had an interesting summary in the New York *Electrical Review* with regard to cables recently put underground for arc lighting service. It goes without saying that such tests are for the present necessarily inconclusive, but so far as they have gone the results are better than might have been expected, and should they be maintained they will show that cable manufacture in this country for underground work has reached a high degree of perfection. Dr. Wheeler mentions that the cable laid last January in the suburb of Harlem over a short route has been in satisfactory operation ever since. With regard to an eight-conductor cable put in for the local Brush Company, and now in use, the fact is brought out that while the insulation of all the conductors is fairly good, two of them do not possess an insulation quite as high between wires as is required by the strict interpretation of the stringent rules of the Board. Probably there will not be a great amount of arc light cabling done for this reason, and the wires will be run individually. With regard to the insulation resistance of some of the cables, it is pointed out that the falling off now and again has been due to the exposure of the many ends of the cables to the atmosphere at the tops of the lamp-posts. Twice in damp weather the insulation was found to be very low, but by warming and drying the wires at the lamps it was very soon proved that the falling off of the whole cable was due to the exposure at these points, and a corollary was that the

Digitized by Google

only part of an underground line that would not maintain a very high insulation during storms is the part that is thus exposed for the purpose of making the connections. Dr. Wheeler adds: "The tests made at the same time with the first-class overhead wires used to connect the underground wires showed that their insulation invariably fell in damp weather far below that of the cables, while, as stated before, when these terminals were properly dry the cables tested nearly as high in stormy as in dry weather."

BERLIN NOTES.

(FROM OUR CORRESPONDENT.)

BERLIN, *May* 5, 1889.

The Safety Appliance Exhibition, which was opened by the Emperor on the 30th ult., contains several electrical exhibits of interest. This Exhibition is the outcome of the Imperial message of November 17, 1887, and its aim is to bring before the public everything tending to minimise the dangers of moving machinery, manufacturing processes, &c., and to add to the health of the people. The electrical section is not confined to fire-alarms telegraphy and such like minor applications of electricity, but includes some heavy engineering exhibits. Among the electrical exhibitors are the Allgemeine Elektricitäts Gesellschaft, Siemens and Halske, the Deutsche Elektricitäts Werke of Aachen, and L. Schwartzkopf, who owns the Gülcher and the Zipernowsky-Déri-Blathy patents. Herr Schuckert, of Nürnberg, of course has some exhibits, but they are of a meagre character. I hope to give you a detailed description of some of the most interesting exhibits a little later.

The Physical Society of Frankfort-on-Main announce the completion of their electro-technical schools, the object of which is to give a theoretical training in electrotechnics to young mechanics who have served their apprenticeship in engineering or electrical workshops. As the fees are low, being only £5 a term, and the schools are well fitted up, the classes ought to fill.

Messrs. Hostmann and Co., of Hanover, are negotiating for permission to run an electric railway between Badenschenem, Baden-Baden, and Lichtenthal. There is considerable opposition to the scheme.

Herr Uppenborn, who has always maintained that all insulation tests should be made with E.M.F.s approximating those which are likely to be employed in practice, has recently published in the *Centralblatt für Elektrotechnik* some tables showing how very markedly the insulation resistance diminishes as the voltage increases. In the case of two cotton-covered copper wires twisted together the insulation resistance when using three cells of 1·7 volts each was 281×10^6 ohms, when using 10 cells it fell to 134×10^6 ohms, and when 16 cells were applied it fell to 121×10^6 ohms. On testing the insulation resistance of the slate base of a safety fuse Herr Uppenborn, when using 3, 8 and 16 cells, found it to be 68×10^6, 45×10^6, and 24×10^6 ohms respectively.

CORRESPONDENCE.

PROF. OSTWALD'S EXPERIMENTS IN ELECTROLYSIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It has been pointed out to me by Dr. Armstrong, my co-secretary on the Electrolysis Committee, with reference to my letter criticising Prof. Ostwald in your issue of April 19 that the experiment I there criticised was only intended by Prof. Ostwald as a hypothetical one, or an experiment on paper. His statement rather is that if one imagined the experiment one could imagine such and such results, and could thence deduce conclusions having a bearing on certain points under discussion, and upholding the doctrine of extreme dissociation.

I thought at the time that most likely the experiment was only hypothetical, but did not like to assume it without clear evidence. In trying to avoid this assumption I may, perhaps, have fallen into the error of seeming to imply that Prof. Ostwald recorded it as an actual experiment with the wilful intention to mislead. If my letter bears this or any other offensive interpretation I beg to express regret.

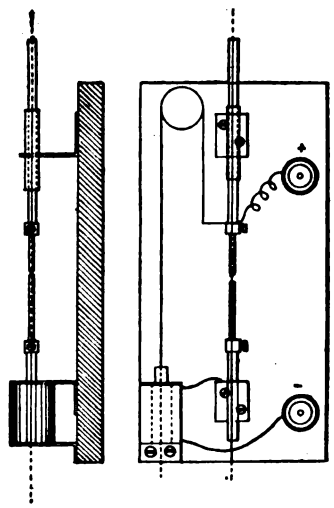
Foreign modes of expression and discussion are probably different from ours, and it may seem natural and useful to discuss hypothetical experiments and to deduce conclusions from them. My feeling runs rather counter to this mode of procedure, and that is all I would wish my previous letter to be taken as expressing.—Yours, &c.,

Liverpool, May 14, 1889. OLIVER J. LODGE.

SIMPLE ARC LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Seeing a sketch of above in your issue of May 3 makes me think the enclosed sketch may be of some interest. Having occasion some time back to give an exhibition of the electric light, and having no lamp at hand, I constructed the one shown out of various odds and ends lying about a workshop.



The solenoid was made from two pieces of brass $\frac{1}{16}$in. thick or so to form the end checks, one of which was bent out as shown to form the foot for attachment to wood base; these were soldered to a piece of $\frac{3}{8}$in. brass tube $2\frac{1}{8}$in. long, and dimensions of coil inside were 2in. long by 2in. diameter; this held $\frac{1}{2}$lb. No. 16 B.W.G. double C.C. wire easily, but 6oz. was plenty. The core was 3in. long by $\frac{5}{16}$in. diameter, and was a shade heavier than top carbon holder and carbon, and was adjusted so that when the carbons were in contact the core protruded about $1\frac{1}{2}$in.

Connection between top (+) carbon and terminal was by a spiral of copper strand; adjustment for current was by weights on top of (+) carbon holder. I found that to get a steady light the core had to be rather more than half-way through solenoid; and to check "hunting" I applied a light spring to introduce friction to the movement of upper rod.

Diameter of carbons, 4 millimetres "Hardtmuth," from Woodhouse, Rawson and Co. (judged from light given) about 6 or 7 amperes.

I may mention that the light was seen four miles off by a man who made out he was shooting wild ducks by the light given, and that in the town some quarter of a mile off it was thought by some that the house was on fire. The light being a novelty there, a crowd of some 200 persons were in the street in front inside of half an hour. The first trial was made with a solenoid consisting of only about one dozen turns of No. 18 braided wire (which we had handy), and stapled to the board.—Yours, &c., GEORGE T. PARDOE.

THE ELWELL-PARKER ALTERNATE CURRENT DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of May 10 we notice a letter from Messrs. Ganz and Co., in which they refer to a statement made by Prof. Forbes in his recent Paper on "Central Stations in Europe," that an alternating-current dynamo manufactured by us is a copy of one of their old-type machines.

We are sorry that the discussion on Prof. Forbes' Paper has not yet been published, as the facts given by Mr. Preece would have shown Messrs. Ganz that our latest machine is only slightly different in details from a machine patented and built by us in 1882, and prior to their patent. We enclose photo-

Digitized by Google

graphs of the 1882 machine, which has a stationary armature, with flat coils laid on the inside and revolving field-magnets, similar to our machine of 1888, of which we also enclose photographs. Machines built in 1882 to the first patent ran very successfully, but at that time, there being no use for alternating-current machines excepting to run Jablochkoff candles, not much was done with them until the advent of the transformer.
—Yours, &c., (Signed) T. PARKER, Director,
For Elwell-Parker (Limited).

7,002. T. H. HICKS. London. Improvements in electric secondary or or storage batteries.

COMPANIES' MEETINGS & REPORTS.

Western and Brazilian Telegraph Company (Limited).

The seventeenth ordinary general meeting of this Company was held at Winchester House yesterday (Thursday), Mr. W. S. Andrews, chairman.

The SECRETARY read the notice convening the meeting. The minutes of the last general meeting having been read,

The following report of the Directors was taken as read;—

"The total earnings amount to £112,250. 6s. 11d., as against £78,369. 18s., showing an increase of £33,880. 8s. 11d. compared with the half-year to 31st December, 1887. The working expenses amount to £31,220. 4s. 2d., as against £30,903. 1s. 6d., an increase of £317. 2s. 8d.

Including the amount brought forward from 30th June, 1888 (£3,293. 16s. 8d.), and the dividend received upon the shares held in the "Platino" Company, the balance to the credit of the revenue account is £98,592. 4s. 5d., from which has to be deducted £13,500 for debenture interest, and £929. 5s. 2d. for expenses and stamps in connection with the transfer of the Platino Company's shares, leaving £84,162. 19s. 3d., of which £7,000 has been placed to the renewal fund and £6,400 to the Debenture Redemption Fund. This leaves £70,762. 19s. 3d. The Directors now recommend the payment of a final dividend of 9s. per share, free of income tax, on the Ordinary shares for the half-year, making, with the dividend paid in November, £5 per cent. for the year. The dividend for the year 1887 was at the rate of £4¼ per cent. per annum.

In the case of shares which have been divided into Preferred and Deferred, 1s. 6d. per share of the dividend now recommended will be payable to the Preferred shareholders, and 7s. 6d. per share to the Deferred shareholders.

The balance remaining is £29,561. 17s. 3d.

The shareholders are aware that there has been, and continues to be until 1910, an annual charge upon revenue of £1,200 to repay to the capital account the discount of £36,000 given upon the original issue of debentures; of this discount £9,900 has been paid off, and a balance of £26,100 remains. The directors propose to apply £26,100 of the balance of £29,561. 17s. 3d. to secure the following advantages:—

1. The paying off the above item of £26,100.
2. The getting rid the annual charge upon revenue of £1,200.
3. The allocation of the £9,900 already paid, and of the £26,100 now to be paid, to the credit of capital.
4. The reduction by these amounts of the necessary capital to be provided for the new cables.
5. The diminution of the annual charge to be incurred on this account.

It is clear that any reorganisation of the Debenture capital referred to in paragraph 14 would be rendered more difficult by a standing debit item in the accounts referable to its issue. There will remain a balance to be carried forward of £3,461. 17s. 3d.

The payment received for the directors' fees in the Platino Company for nine months, £900, has been placed to the credit of the capital account, so that the sum originally paid as compensation will be gradually returned. Of the total amount that may be required to provide for the making and laying of the loop cables, £36,000 is provided by the repayment made to capital account. The Company has power to issue £50,000 of debentures ranking with the present "B" debentures, and the balance which may be needed will be taken from the renewal fund. The loop cables when laid will largely tend to ensure uninterrupted communication over the Company's line, and this additional security will entail only a very moderate charge upon revenue.

The debentures will be offered to the proprietors when required to be issued. The annual drawing of the existing "A" and "B" Debentures at

Digitized by Google

par will commence in February next year, when £11,200 will be drawn, and from that date the debentures will be redeemed by progressively increasing drawings. The directors referred the question of replacing the existing debenture debt of the Company by permanent debentures at a lower rate of interest to the Company's solicitors and counsel, who have advised that any measure affecting the status of the existing debentures will require the individual assent of all the holders.

Since the last half-year's report 1,310 "Platino" shares have been transferred by shareholders in exchange for 786 shares of this Company."

The CHAIRMAN then said it had been his pleasing duty on the last few occasions that the shareholders had met to congratulate them upon the continuous increase of traffic with which the concern had been favoured. He was pleased to say that to-day formed no exception. The traffic for the last half of 1888 was the largest traffic that they ever had in one half-year since the undertaking had been formed. The corresponding half-year was a very satisfactory one, but the last showed, as compared with it, a receipt of £112,250, the previous receipt having been £78,369, and the increase, December, 1888, compared with December, 1887, was therefore £33,880; that, of course, was eminently satisfactory. It appeared to him that it would be equally satisfactory to them to learn that the large increase of nearly £30,000 had been earned at an increased expenditure of £317. 2s. 5d. He did not think that many companies could call in so large a receipt as that with so small an increase of expenditure. This increase, they find, had arisen at the stations abroad, in the salaries and wages, and an increase which was attributable to a largely increased payment on account of the high rate of exchange which they had heard of previously; to certain increase of staff, and to a bonus which the Directors had to give to the staff on account of the expenses of living, additional work, &c.; and considering that these men had done all the actual work of earning an increase of £33,000, he did not think the shareholders would object to it. The other items were very small. Taking Abstract B, the cost of ships, they had an increase of £837, nearly all for additional stores supplied to the "Norseman," and a decrease of £1,020 arising through a lessened expenditure on account of coal. They were fortunate enough to effect charters for both steamers, from which a sum of £1,323 had been derived; so that, deducting that and the other savings from expenditure, they had considerably reduced the expenditure in the two ships. Under Abstract C, expenses at home, which, though shareholders—and very properly so—generally looked at with a considerable amount of attention, there was an increase of £226, less a decrease of £33, being a net increase of £193, which covered all the additional labour consequent on increased business. This they might regard as being satisfactory. On the 1st of April considerable reductions were effected in the rates between this country and Brazil, in order in the one direction to develop the communication by telegraph between this and the neighbouring countries, and in order also—and that was a very important element in the consideration of the question—to satisfy customers. Customers appeared to have what was termed by Mr. Disraeli an ignorant impatience of taxation; they always cry out "high tariff," because whatever it is, customers always call it high. They always want a lower one if they can get it. They had hoped by the time this meeting was held that they would be able to tell them something as to the effect of the reduction in the tariff, but most unfortunately the line between Pernambuco and Rio broke down on March 31. As if that was not sufficient, the line broke down between Rio and Santos on April 15, and on the very day of the repair of the first break, between Pernambuco and Rio, the line between Grandu and Chili broke down, on April 25. These breaks, of course, have taken up a great deal of time. All the lines were repaired on May 15. Of course that being so recent, it is impossible to calculate what share of the loss of receipts had been occasioned by interruption, and what share of the lessened receipts was due to the reduced tariff they have no means to arrive at; but one thing they had arrived at in their own minds, namely, that these accidents proved the necessity and the wisdom of the policy which the shareholders determined to carry out, of laying these loops. If these loops had been down instead of being projected they would probably—he did not say certainly—have been in the enjoyment of the full amount of revenue. There was no doubt that certainty of communication with these loop cables tended to keep and develop a large trade, and it is an encouragement in the direction of an increase of business consequent upon the reduction, because the business would be reliably done. They could not tell the impulse that this would give to the trade yet; probably they would shortly With regard to the loops, a shareholder had approved of other precautionary methods in the shape of preserving the reserve fund; the Directors had to look about them, and, with the policy of the shareholders in their minds, to see in what way they could effect the laying of the loops. One thing which had struck them was that they had 50,000 of "B" Debentures unissued which would rank with the existing "B" as regards the charge they held on the Company's effects, and which, therefore, would stand pretty well as to terms per issue. They must not suppose that the Directors were thinking of issuing these Debentures at 6 per cent. interest; they had no idea of doing that or anything of the sort. Turning their attention, however, to Preference shares, the same objections applied; they could not either issue Ordinary shares at discount as it was illegal. The Directors were driven back, as it were, upon what they could put their hands for the benefit of the shareholders. Having reached that, matters were very much simplified. There were only two methods of dealing with the thing as far as they could see—the one was the issue of £50,000 of Debentures, and take the whole that might be required from the reserve fund; and when they came to consider they found it was impracticable, because it would deplete the reserve fund to such a large extent as to very much weaken the soundness of their financial position; and consequently, after careful and exhaustive examination, they arrived at the result communicated in the report to the proprietary body. There was on the one side of the account a very unsatisfactory item of discount on the old issue of Debentures, which was not a pleasing item. It was not an item which would assist the Board in the reorganisation of Debentures; in fact, it was necessary that it should be got rid of, because if they got rid of it they got rid for a great many years of an annual charge of £1,200, which became realised for the general purposes of the Company. This was, therefore, looked at with a favourable eye, together with a further sum of £900 paid to the Western Brazilian Company by the Platino Company in liquidation; and looking at the terms at which the Debentures could be issued, the Directors thought they saw their way without touching the reserve fund at all. As regarded the issue of Debentures and payment for the cables, of course that would not all be required at once—perhaps not for a year. The first operation they would bring into effect was the use of the cash they had; the second would be the sale of a certain number of securities as might be required for the renewal fund; and the balance would be the issue of Debentures, which would take place last of all. These Debentures would be offered to the proprietors, and he hoped a good many would come forward and take them. They had not been able to go further with respect to the loops than to consider the best way in which they might be laid. They could not do anything positive until the shareholders approved of the plans. It was probable expeditions would have to be sent out, but that had not been fixed. When they knew the policy of the shareholders they would immediately set to work to put the thing into one shape or another. There was a subject he was bound to touch upon. They had been informed that a circular had been issued to a number of shareholders inviting them not to give their proxies to the Board, but to certain gentlemen who were named. There was no reason to complain of that, but it was a somewhat extraordinary position for gentlemen to take up before they knew what the policy of the Board was. These gentlemen also did not inform us what their opinions were, nor upon what ground they desired the proxies in their favour. They might have come to them and stated their views, and we could have seen if we could meet them. He would conclude by moving the adoption of the report and the payment of a dividend of 5 per cent.

Questions were then asked by Messrs. GUESDEN and GROVER, which were answered at some length by the Chairman.

A resolution was then put by Mr. COPPIN, seconded by Mr. WEDGWOOD, in opposition to the report, which was negatived.

The report was then adopted by a large majority.

The retiring Directors were re-elected.

Mr. Griffiths was appointed second auditor along with Mr. Weise.

A vote of thanks to the Chairman then brought the proceedings to a close.

The West Coast of America Telegraph Company (Limited).

The twelfth ordinary general meeting of this Company has held on Wednesday last, at Winchester House, Old Broad-street, Mr. Alfred Marshall presiding.

The SECRETARY (Mr. Fred. L. Robinson) read the notice convening the meeting, and the minutes of the last general meeting. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, you have all had a concise and complete statement of the business of the past year, so that I have very few remarks to add to what is presented to you in the report. The chief feature of the accounts is the large increase of £7,820 in the gross earnings of the Company during the past year. Doubtless you will agree with me that this is a satisfactory increase. I now come to the other side of revenue account, and it is an equally pleasant feature that this great increase has been accomplished with an increase of only £289 in the expenditure account. Going more into the details of the expenditure account, you can see that the West Coast expenses, which include salaries and stationery, and so on, have increased in proportion to the work done. On the other hand, we have been fortunate in having very few interruptions in our working during the past year, so that the smaller expenses of our repairing steamer, and the smaller expenses in the maintenance of the cables, about compensate for the increase of working expenses. I can only express a hope that during the current year we may be as free from those unpleasant interruptions which cables are naturally liable to as we were during the last twelve months. We shall keep our steamer ready at a moment's notice to repair any damage that may occur. We have been generally successful in keeping down interruptions to within a few days. You will see that we are able to place a very handsome amount to our reserve this year. At the same time I wish it were even larger, and I hope during the present year, if we go on as steadily as we have done hitherto, that we shall be able to recommend that even a larger sum should be placed to reserve. There has been a very good trade on the coast, and a great many companies have been formed during the past year, and I think that has materially assisted to bring up our earnings to the satisfactory figure we can show. We can hardly expect that as many companies will be formed during this year as there have been lately; but the tendency of telegraphy is to increase, particularly if, as we hope to be able to do, we reduce our rates a little in proportion to the increase in our earnings. You will see that amongst our assets in the balance-sheet there appears an item of £4,000, which was the cost of the land line between Valparaiso and Santiago. We thought it of great importance to get into direct communication with the capital, and for that purpose we acquired a concession to lay a land line between Valparaiso and Santiago; but after we got the concession the people working the existing line, which had been in operation for several years, approached us and offered to sell their line to us, the terms which they gave

Digitized by Google

to us being according to our ideas satisfactory. We thought it better to acquire the existing line and to be able to commence working at once, and at the same time avoid competition. I am glad to be able to say that our expectations have been realised by good work on that new line. We have increased the earnings, and we are getting a satisfactory return for the capital laid out. Besides this increase to our line, we have made arrangements for direct communication between Iquique and Pisagua, which is one of the nitrate ports. At one time there were as many as eighty ships in it, which shows the great importance of the port, and every ship means more or less traffic for us in communicating with the captains, and so on. You will all, no doubt, sympathise with us in the loss of our late colleague, Mr. Campbell. He was a conscientious, hard-working man at the board, and we are very sorry to be deprived of his services by death. He concluded by formally moving the adoption of the report and accounts.

Mr. FREDERICK WALTERS seconded the motion.

Mr. L. WELLS said he rose with great pleasure to congratulate the Directors on the satisfactory state of the accounts. He wished, however, to make one or two remarks on them. Since he had become a shareholder in the Company twelve months ago he had taken a great interest in its welfare, and had watched the published returns of the traffic which had appeared monthly. He had taken out the figures for 1888 each month separately, and the total aggregated £59,775, but in the statement before them it appeared to have been £64,583, or a very satisfactory addition of £4,808. Perhaps the Chairman might explain the cause of the difference. It was a very satisfactory increase, and was no doubt capable of explanation. The other topic to which he would call attention was the reserve. On one side of the balance-sheet it appeared as £27,000, to which according to the report they had added £12,000, raising the total of the fund to £39,000. On the other side of the balance-sheet he observed that the investment account figured at £33,203, showing that the Directors had invested any surplus money which they had in hand. But in that account—and he mentioned the subject at the last meeting—he thought it would be better if the Directors gave the particulars of their investments. All the other telegraph companies without exception gave those particulars, and there could be no motive for keeping back the information, because the shareholders had every confidence in the Directors, and were quite sure that the fund was very well invested. It would really tend to give confidence to the shareholders generally if they could see that their money was invested in such securities that were easily convertible, and prove that the reserve fund was really and actually what it professed to be.

Mr. GARDNER said that he was greatly in favour of adding to the reserve fund. He would have preferred to receive 5 per cent. dividend this year than 6 per cent. if they had, instead of giving 6 per cent., added 1 per cent. more to the reserve fund. He wanted to see the hands of the Directors strengthened, in view of the heavy responsibilities they had to meet in paying off their debenture liabilities.

Mr. WELLS quite agreed with the previous speaker, that the reserve fund should be increased, but not necessarily at the expense of the dividend of the shareholders. The receipts for the first four months of this year showed a very large increase over the corresponding months of 1888, and this increase might fairly be divided between the shareholders and the reserve fund.

The CHAIRMAN: We are very anxious to have a large reserve fund. At the same time we are also desirous of satisfying the legitimate aspirations of every shareholder to receive a fair dividend for his investment. Mr. Wells has asked me to explain the apparent discrepancy between the earnings which are published in the newspapers and the gross earnings which we give in our report. The gross earnings in our report contain not only the traffic receipts but also the earnings of our repairing steamer. We have an arrangement with a neighbouring Company by which they pay us what I may call a retaining fee—a very large round sum—which helps materially to keep down our expenses. We keep our steamer at Callao, which is the connecting point between our own line and that of the Central Company further north; and our arrangement is this, that the Company whose cables are first interrupted has the first use of the steamer. They pay us £6,000 for this consideration, not having a steamer of their own. I think you will say this is satisfactory. As regards the reserve fund, the investment account is mentioned in our balance-sheet at the amount at which it stood on December 31. It does not include any investments made this year out of present earnings, but part of our reserve may be said to consist in stocks of the cable.

Mr. WELLS: That appears in the balance-sheet.

The CHAIRMAN: Yes. As to our giving details of our investments from the commencement, we have adopted the plan of not publishing them, and we always consult our auditor and are guided by his recommendations in making investments. We never make any without his approval.

Mr. WELLS: Every other company gives the details of the investment account.

The CHAIRMAN: We held our own debentures formerly, but the auditor did not think it the right thing to do. We have consequently during the last year realised them at a good profit beyond what they cost, and invested in more convertible securities.

He then put the resolution in the usual way, and it was carried unanimously.

The CHAIRMAN next moved—

"That a final dividend at the rate of 1 per cent., free of income-tax, making 6 per cent. for the year, be declared, payable on the 16th inst."

Mr. HENRY ROBERTS seconded the motion, which was carried unanimously.

On the motion of Mr. ROBERTS, seconded by Mr. C. E. MASON, the retiring directors, Mr. Alfred Marshall and Mr. Frederick Walters, were unanimously re-elected to their seats at the board.

Both these gentlemen having briefly acknowledged their re-appointment

Mr. WELLS proposed, and Mr. LAMONT seconded, the re-appointment of Mr. J. Weise as auditor of the Company. The motion was carried *nem. con.*, and a vote of thanks having been passed to the Chairman, the proceedings terminated.

The Maxim-Weston Electric Company (Limited).

The statutory first ordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street, Mr. John Marks presiding.

The SECRETARY (Mr. Samuel J. Boyce) read the notice convening the meeting.

The CHAIRMAN: Gentlemen, as you will have gathered from the notice just read, this is merely the statutory meeting, and, therefore, a meeting of a purely formal character, called in compliance with the Act of Parliament, which says that within four months of the registration of any new company the statutory meeting shall be held. There is, therefore, really no business for us to transact to-day, and there is no resolution for the Directors to put before the shareholders; but now that we are here I may take the opportunity of making a few remarks, and in the first place I have to inform you that we have unfortunately lost the services of two of our Directors—Mr. Harvest, who we regret to say has been taken from us by death, and Mr. Hildyard, whose business requires the whole of his time and attention, thus necessitating his resigning his seat at the board. On the last occasion we met it was for the confirmation of special resolutions for the reconstruction of the Maxim-Weston Company, I think. I may mention that since then we have had applied for, and have allotted, out of the 312,000 shares, 262,000, so that the whole of the number that we were able to allot in the new company have been allotted with the exception of 50,000. Now that I am on this point I may mention that the liquidators have requested the Directors to offer to the shareholders these 50,000 shares if they are disposed to take them up. I may mention that at the time applications were made for the new shares a very large number of shareholders indeed applied for more than they were legally entitled to under their holding in the old company. Now if those shareholders, and, indeed, any other shareholders, are desirous of tendering for any portion of those 50,000 shares with the understanding that in addition to the price at which they tender there is a liability of 1s. beyond that, because they are 3s. shares, with 2s. credited as paid up, we shall be happy to consider their applications. We are not particularly anxious that the shareholders should take them up, because we could place every one of these shares within twenty-four hours of the present time; but we think that the shareholders should have the option of taking them if they think fit. We therefore invite them to tender for the same, with the understanding that the tenders must be lodged within seven days of the issue of the circular we are now preparing to send to the shareholders. The dissentient shareholders in the old company represented 24,000 or 25,000 shares, but I am happy to say that we have been able to arrange terms of settlement with the whole of those dissentients, on what we consider fair and equitable grounds. We shall therefore, I am pleased to say, have no litigation whatever with the dissentient shareholders. Since our last meeting we have been fortunate in securing the services as general manager of Mr. Hamilton, who may not be known to gentlemen outside the electrical world, but who is very well known to those who are connected with electric lighting; and I am sure he will be a very valuable acquisition to the Company, and we hope with his aid to be able to do such a business as will enable us at the end of the financial year to come before the shareholders and give a good account of our stewardship. I may tell you that we have concluded some contracts, and others are now in negotiation. One contract of an important nature is for the laying down of 1,000 lights. I do not propose mentioning publicly where that installation is, but if any shareholder is desirous of knowing that, we shall be pleased to give him the information if he will apply privately for it at the office of the Company. We do not think it is advisable to state publicly where we are carrying on work; but this is an installation which, although an important one in itself, is likely to lead to far greater results in the same direction, and from which we hope to realise profitable returns. If there is any information that the shareholders wish now, we shall be happy to give it. We can only say that we consider we are going on in a very satisfactory manner, and we hope, as I have said before, that at the end of the financial year we shall all come before the shareholders and give them such an account of our stewardship as will be satisfactory to them and to the Directors.

A SHAREHOLDER asked when the next call of 6d. per share would be made.

The CHAIRMAN said it was due six months from the date of the reconstruction of the Company, or two months from the present time. He had no doubt that the call would have to be made at the proper time.

A SHAREHOLDER asked what stage the pending legislation between Mr. Watt and the Company had reached.

The CHAIRMAN said that they hoped that their action against Mr. Watt would soon be down for hearing. The Company's claims against Mr. Watt amounted to about £4,000, while that gentleman's claims against the Company amounted to £1,700.

The proceedings then terminated.

Newcastle and District Electric Lighting Company (Limited).

The first general meeting of this Company was held on the 13th inst. at Newcastle, "to receive the report of the Directors as to the progress of the Company, and to transact the other ordinary business of the Company." On

Digitized by Google

the motion of Sir B. C. Browne, seconded by the Hon. C. Parsons, the chair was taken by Mr. J. D. Milburn.

The CHAIRMAN said this was a meeting which they were obliged to hold under the Act, which enjoined that a general meeting of the Company should be held within four months of its registration; and it was customary on such occasions to give the shareholders a report of the progress of the work. It was necessary to consult the local authority and get them to acquiesce in the establishment of the Company; and in regard to this the Company had had very little trouble with the authority. They had then to make application to the Board of Trade for a license; and two months' notice of this had to be given in order that anybody objecting to the establishment of the Company might have the opportunity of doing so. The notice would expire on the 26th inst.; and, so far as the Directors knew, there was absolutely no opposition. The Directors hoped by the end of May or the beginning of June the sanction and license of the Board of Trade to commence work would be obtained. In the meantime the Directors had made several important contracts. The dynamos and engines had been partly contracted for, and he believed they could be ready almost immediately. All the boilers required for the first section of the work of the Company had been contracted for, and would be delivered at the end of June or early in July. The Directors, after consideration, had chosen at the Forth Banks a site for their central station; and as soon as the Board of Trade license was received would erect the seatings for the boilers and also chimney; and the Company would begin to lay cables in order to supply the current to customers. The system of lighting adopted by the Company was that of the moderate tension of 1,000 volts; and it was thought that with this system—which was pretty familiar to most electric lighting companies—the Company would be able to efficiently light the area round about. The Company not only pretended to light Newcastle, but had power to light the district; and they might have to adopt a higher tension, something like 2,400 volts alternating current, or even more; and under these circumstances the Directors thought it wise to lay such cables and such transformers as would carry the heavier voltage. The machines adopted were those of the turbine system now so well known in this district, such as had been supplied to a great number of steamships and works, and were giving very great satisfaction. These turbine engines had been ordered from Messrs. Clarke, Chapman and Parsons, and were being constructed with the very greatest care; and he had no doubt they would give every satisfaction to the Company. The boilers, three in number, of the high pressure of 140lb. to the square inch, were being made by Messrs. R. and W. Hawthorn, Leslie and Co., at their works adjoining this Company's station at the Forth Banks. It had been a particular order of the Directors to have more boiler power than was even necessary for the first section. So much for the work which had been going on in the way of erections; and he would now say a few words in regard to the business operations of the Company. The business staff of the Company had not been idle; they had been canvassing all along, and more particularly of late, and at the present time there were signed applications for lighting amounting to 35,000 candle-power incandescent lights, or 3,500 lamps of 10 candle-power each, which was about half the amount required to keep the first section fully going. The Company were daily increasing their connections. Tradesmen and others likely to make use of the light, seeing that the Company were going about the matter in a business-like way, were giving every attention to the members of the staff who called upon them; and there was no doubt that in a very short time there would be more business than the first section of the work would be able to undertake. The Directors were determined upon two or three things. The first was that they were resolved to give a good steady light; and, the second was that they were going to ask a fair but sufficient price for it Several electric lighting companies had come to utter failure, and ended in disaster; and there were, he thought, three reasons for this: the first reason was the heavy initial expenses; second, a bad selection of machinery, cables, &c.; and third, asking a price totally inadequate for the work they were going to undertake. There must be a great many unknown elements in such a new thing as electric lighting; and some of those companies had the absurd and Quixotic idea that it was their duty to enter into a death struggle with gas right away. The Directors of this Company did not hold such an opinion. Gas has been a useful servant in the past, and when it had become a thing of the past, so far as an illuminant, it would continue to be a good servant for many other purposes. The Directors did not intend to go to war with gas, but they intended to give a light of a higher order than gas, and would charge a price somewhat higher—nominally higher, because it would be a matter of calculation whether that price would be really higher or not. By using the electric light there would be a great saving in the damage done, especially in large warehouses where delicate fabrics were stored; and it would also prevent damage in picture galleries. It would be a much healthier light for theatres, concert rooms, and ball rooms, for the electric light, by its incandescence, absence of heat, and more especially the utter absence of any noxious fumes, allowed the air to be entirely unvitiated, and rooms to be properly ventilated. The price which the Company intended to charge was 5s. for 10,000 watt-hours, which was 6d. per Board of Trade unit, with varying discounts according to the quantity of light taken. There were twenty-nine or thirty customers' names in the Company's books who had already begun to have wires placed in their premises, and who were quite content with the price. The capital of the Company was nominally £50,000 in 5,000 shares of £10, but it was proposed to issue only 2,000 shares at present. There had been 1,200 to 1,400 shares allotted, which were subject to £7. 10s. being called up. More than this number were applied for some time ago, but, upon the suggestion of Mr. Parsons, the managing director, applications were in some cases cut down, and the assurance was given to applicants that an opportunity to take more shares would be given them after the prospects of the Company had been more clearly ascertained. Now that the future prospects of the Company seemed to be fully assured, and no opposition being offered to the granting of the license of the Board of Trade, and the Directors having every confidence in the successful working of the Company, it was proposed to open the list to the end of the week to close up the amount required for the first section; not that it would all be required, but the more shares subscribed the smaller would be the amount to be called up. The Directors did not fear anything about capital; they thought the difficulty hereafter would be to refuse capital. They did not intend to go on too rapidly; they intended to win station by station, and at each succeeding station they would take advantage of all known improvements. The Directors were determined to do their very best to make the Company a great and established success, without entering into any Quixotic competition with anybody.

This concluded the ordinary meeting, after which an extraordinary general meeting was held to consider and approve the proposed Articles of Association of the Company.

Mr. W. S. FINDLAY moved that the Articles of Association be adopted.

Sir B. C. BROWNE seconded the motion. He said the company had been exceedingly fortunate in having obtained the services on the Board of Directors of Mr. A. Wade, who was connected with the London Electric Supply Corporation, which had hitherto been treated at the Grosvenor Gallery, but had now started enormous premises at Deptford, which would be by far the largest and most important electric premises in the world. Mr. Wade was associated with those works; and having Mr. Wade as a Director this Company was connected with the very front rank of the electric lighting movement, and this he hoped might be considered another guarantee for their success. Lord Crawford, another Director of the London Electric Supply Corporation, was also one of the original shareholders in this company.

Mr. W. M. ANGUS and Mr. A. WADE each spoke in support of the motion, and it was agreed to unanimously.

On the motion of the Hon. C. PARSONS, seconded by Mr. FINDLAY, a vote of thanks was passed to the Chairman, and the meeting concluded.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.

Woodhouse and Rawson (Limited).

The following is the report of the Directors to be presented at an extraordinary meeting of this Company, to be held at the Cannon-street Hotel, on Friday (this day), at three o'clock. The meeting will be further asked to sanction the declaration of a dividend and to consider and, if thought fit, to pass the following resolution :—

"*The agreement,* a draft of which has been produced to this meeting and initialled by the Secretary, is hereby approved, and the Directors are hereby authorised to enter into the same and to carry the same into effect.*"

The accounts show a profit for the second six months amounting to £9,771. 13s. 3d., making a total profit of £21,440. 2s. 11d. for the year. Of this amount the Directors propose to transfer £12,000 to a reserve account, and from the balance, £9,440. 12s. 11d., to recommend a dividend at the rate of 12 per cent. per annum for the half-year ended June 30th last on the amounts paid up at that date, which, with the interim dividend already paid, will make 12 per cent. for the year ; this will absorb, say, £8,000, leaving £1,440. 2s. 11d. to be carried forward.

With regard to the working of the Company, the installation department maintains its character for high-class work, and it is found that a good class of wo k is obtained, and that through the best advertisement—that of the recommendation of clients.

The foreign business has assumed such large proportions as to justify the expectation of profits far in excess of anything previously anticipated. Contracts have been recently signed whereby the company will not only obtain a very large sale for its various manufactures and commodities in one of the principal countries of Europe, but also secure a large immediate profit. At present there are negotiations abroad for a contract for the supply of double the present output of incandescent lamps for five years, and there is every reason to hope that the negotiations will be successful.

Of the subsidiary companies in which this company holds a large interest, the Woodhouse and Rawson Supply Company of Great Britain (Limited) has done especially well, and there has been a great increase in its general business. This company supplies every class of electrical requirements, as is shown by its price lists, which are the most complete of the kind.

Returns furnished by the Woodhouse and Rawson Electric Contract and Maintenance Company, Limited (Lancashire, Yorkshire, and Cheshire), show a steady and gratifying improvement, and the supply of current from the electric light station put up by the Bradford Corporation, which is expected to be shortly available, will lead to a large increase of the business.

The Woodhouse and Rawson Electric Manufacturing Company (Limited) has large orders in hand for electrical work, and has obtained the sole manufacture of several important specialities during the past year.

At the extraordinary general meeting of shareholders, held on the 14th of December, 1888, the chairman gave a detailed account of the progress of the Company's business during the year 1888, and explained that the further development of it made it desirable to increase its working power by the formation of a large company, formed to take over this and other undertakings. He also explained that the amalgamation of this Company with its subsidiary companies would be very desirable for several reasons ; amongst others, it was practically the only way to put an end to the Founders' Shares, which are now entitled to so large a share of all the profits beyond 10 per cent.

The arrangements are now nearly complete for the formation on very satisfactory lines of the new company already referred to, which will take over the business of this and other Companies, and it is expected that it will be brought out in a very short time. The shareholders in Woodhouse and Rawson (Limited) will under the proposed scheme receive fully-paid shares of the new company to the amount now paid up upon their shares, and in addition thereto a bonus of 10 per cent. thereon, half the amount to be issued to them being in Preference shares and half in Ordinary shares. It is also intended, in addition to paying the dividend mentioned above, to distribute certain assets reserved to this Company by its agreement with the new company.

The agreement, together with details of the new company, will be explained to the shareholders at the ensuing meeting.

* The agreement referred to is with a view to carry out with some modifications the scheme for the sale of the property and undertaking of the company to a new company, which met with the general approval of the shareholders at the meeting on December 14, 1888. The terms of the agreement are to be explained to the meeting.

NEW COMPANIES REGISTERED.

CROMPTON-HOWELL ELECTRICAL STORAGE COMPANY (LIMITED).—This company was registered on the 3rd inst. with a capital of £19,600, in six founders' shares of £100 and 19,000 ordinary shares of £1 each, to carry on the manufacture and sale of secondary batteries, and to take over the business of the Crompton-Howell Electrical Storage Company. The first subscribers are :—J. Albright, Mansion House-buildings, E.C. ; J. C. Howell, Caeffain, Llanelly ; H. Laurence, 29, Grove Hill-road, S.E. ; G. Hartmans, 28, Hartington-road, Ealing ; H. Dowsing, 4, Queen Victoria-street, E.C. ; F. Reeves, Springfield, Potter's Bar ; L. Maton, 21, Cannon-street, E.C. The number of directors is not to be less than four nor more than seven. The first are R. E. B. Crompton, W. Albright, G. Albright, J. Albright, and J. C. Howell ; qualification, £500 shares ; remuneration, £50 per annum each.

MEXICAN SOUTHERN RAILWAY (LIMITED).—Registered by Ashurst, Morris, Crisp and Co., 6, Old Jewry, E.C., with a capital of £1,000,000 in £10 shares. Object, to construct or acquire and equip, maintain and work railways, tramways, lines of telegraphs, telephones, or other means of communication or appliances of a similar nature in the Republic of Mexico ; to acquire mining powers, rights or easements over any railway, tramway, or line of electric wire ; to carry on the business of carriers of passengers and goods in all its branches by land and water, and that of transmitters of messages. The number of directors shall not be less than three nor more than nine ; the first to be appointed by the subscribers to the Memorandum of Association. Qualification, £250 stock. Remuneration, Chairman £1,000 ; other directors £400 per annum.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 3, 1889, amounted to £2,844, and for the week ended May 10 to £3,086.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the weeks ended May 3 and 10, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were respectively £1,939 and £2,147.

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—The first general meeting of this Company will be held on Friday, May 17, at the Cannon-street Hotel, at 12 noon.

SUBMARINE CABLES TRUST.—In the report of the Submarine Cables Trust for the year ended April 15, it is stated that the balance of 7s. 6d. on the coupon due October 15, 1883, will be paid on the 15th instant.

THE BATH ELECTRIC LIGHT COMPANY.—The directors of the Bath Electric Light Company (Limited), whose registered office is at 2, Northumberland-buildings, have issued a circular in which they regret to state that the amount of share capital necessary for carrying out in its entirety the scheme of electric lighting for the City of Bath has not been subscribed. "It is," the directors add, "further to be deplored that this state of things has been brought about in a great measure by misrepresentation of facts on the part of those whose personal interests are supposed to be assailed by the introduction of the electric light. The matter is, however, so important to the citizens at large that the directors feel it incumbent upon them to state that unless at least £10,000 additional capital is applied for before the 27th inst. they will not feel justified in adopting the provisional contracts which would enable them to lay down the necessary plant for private lighting. The public lighting is, of course, already assured ; but in view of the generally expressed desire to have the means for private or internal lighting it is hoped that the citizens generally will see the necessity of subscribing to an undertaking which would supply this want."

REMOVAL.—"Wyman's Technical Series."—The publishing office of this valuable series of practical handbooks has been removed to 65 and 66, Chancery-lane, W.C.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

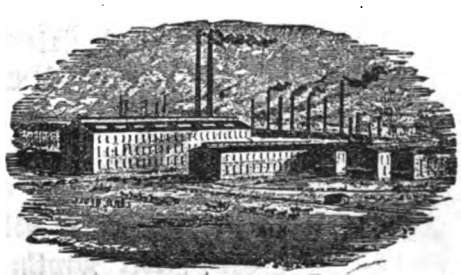
This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.



FACTORY.

FLEXIBLE, 2/- per lb. ; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 575.—Vol. XXIII. FRIDAY, MAY 24, 1889. Price Fourpence.

NOTES.

With the report of Major Marindin we have dealt in another column, but there arises out of it incidentally a matter of great importance, to which we may refer in this place. The question whether or not an Order or a License is to be construed, in the absence of a contrary provision, as conferring a monopoly within the scheduled district during the period of its operation appears to have been tacitly decided in the negative. The districts of Chelsea, and of St. James, Westminster, which have been allotted to the London Company, are already occupied in part, the former under an Act obtained in 1886 by the Chelsea Electricity Supply Company, and the latter under a License granted last year to the St. James and Pall Mall Electric Light Company. For good or for evil, therefore, the principle has now been established that statutory powers under the Electric Lighting Acts convey no monopoly whatever.

The Paper read last night before the Institute of Electrical Engineers by Mr. W. M. Mordey on "Alternate-Current Working" was full of the liveliest interest from beginning to end; it is, indeed, seldom that the Institute has the opportunity of hearing a Paper embodying the results of so much practical research, and tending at the same time to overturn so many widely accepted beliefs. Mr. Mordey's Paper is equally remarkable for the fearless manner in which he presumes to differ from nearly all the guides, philosophers and friends who have preceded him in the treatment of the subject, and for the courteous, and, we may add further, the highly effective way in which he expounds his reasons for so doing. In the first place, Mr. Mordey has settled by direct and conclusive experiment the question of working alternators in parallel, and has shown that—contrary to all that we have hitherto been told—this is to be done by reducing to a minimum both the self-induction and the resistance of the armature. It will be remembered that the smallness of its self-induction and the rigidity of its field are features characteristic of the Mordey Alternator, and he has found that if two such machines are switched into parallel circuit under almost any conceivable conditions they will instantly fall into step. They may be giving widely different E.M.F.'s, they may be loaded or unloaded, their phases may at the moment be in opposition, they may even be driven by different engines at different speeds, and still (provided in the last case that one engine is not too powerful) they will instantly adjust themselves for parallel working. Mr. Mordey proceeds to show that this experiment also affords the solution of the synchronising alternate-current motor, which is well adapted for the transmission, though not perhaps for the distribution of energy.

The question of Periodicity is discussed at some length, the author giving his opinion in favour of a medium frequency of about 100. He has found that with this particular period his own transformers have a maximum efficiency—a fact of considerable theoretic interest, which will, however, bear further elucidation. In this section Mr. Mordey furnishes a valuable table, based upon Sir William Thomson's formula, and showing the virtual resistance of conductors of different diameter under periods of 80, 100, and 133. He also proposes a novel and simple method of determining the efficiency of transformers, which though demanding a good deal of time, is well adapted for commercial employment. It consists in determining the power in watts required in order that a direct current may raise the transformer to the same temperature as that at which it arrives when working in the usual way under the given load.

As we shall probably return to this subject after the discussion which takes place on Thursday next, we will content ourselves for the present with a bare enumeration of the remaining sections of the Paper, each of which contains much that is both novel and important. They are as follows:—The Secondary E.M.F. of Transformers; Alternate-Current Arcs; Safety and Safeguards; Hysteresis and Eddy Currents.

The second evening of the discussion on Dr. Lodge's Paper on Lightning Conductors gave rise to several speeches of an interesting character. Col. Armstrong, on behalf of the War Office, announced that they would be happy to supply the barrel of gunpowder for Mr. Preece's experiment. Mr. G. J. Symons thought that Mr. Preece, whilst grasping the rod, should be otherwise well insulated from earth. But on this point opinion seems to differ. Prof. Hughes referred to the experiments carried out in 1864 by Prof. Guillemin and himself with the view of determining the conditions under which a telegraph instrument, or its equivalent, could be protected from a Leyden jar discharge when the discharge was effected "with the utmost possible suddenness"—though since discharging tongs were used it is probable that this condition was not fully attained. Prof. Hughes found—and he is, we think, fully entitled to the priority of the discovery—that under the cir-

Digitized by Google

cumstances of the experiment a thin iron wire was not protected even by the interposition in parallel of "a short, thick copper rod." A translation of the original Paper by Prof. GUILLEMIN, and a discussion on the subject between Profs. LODGE and HUGHES, appeared in *The Electrician* of July 13th, 1888. The difference between them seems to be that Prof. HUGHES is not inclined to draw the inference from the experiment that it would otherwise seem to warrant.

GREAT interest was taken in Mr. WIMSHURST'S experiments showing the difference in the behaviour of positive and negative electricity. It has been known for more than fifty years that between a small ball and a larger one a larger spark can be obtained when the smaller ball is positive than in the opposite case. FARADAY—who in 1838 refers to the fact as being already well known—made a careful study of the phenomenon (*Experimental Researches*, § 1,480, *et seq.*), and found that it depended in part upon the nature of the dielectric, and that in certain gases (N and H) the effect was reversed. He made use of an "analyser" similar to that shown by M. WIMSHURST. A good deal of information on the subject may also be found in "DE LA RIVE" (Vol. II., Ch. I., § 5, edition of 1854). But, so far as we know, before Mr. WIMSHURST no one had observed the remarkable difference in the protective power of points, according to the difference in the sign or direction of the discharge. Mr. WIMSHURST'S experiments plainly showed that under similar conditions a lightning conductor would afford protection when the clouds were negative, but not if they were positive. Mr. WIMSHURST'S observations on the increased tendency to side-flash due to defective earth were also of much practical importance.

IT is possible that some of our readers, on referring to the authorised report of the entire discussion, which we publish this week, may be inclined to think that our criticism of last week was a little unfair. We beg, however, to assure them that the explanation lies in the fact that while the report is authorised the criticism was not. The debate was left almost entirely in the hands of the older men, but we believe that the great majority of the younger school are inclined to attach more importance to the views of the author of the Paper than is generally entertained by the members of the Lightning Rod Conference. We may remark, in conclusion, that of those who alluded to the subject one speaker alone had not yet been able to make up his mind one way or the other on the relative suitability of iron or copper—this was Sir WILLIAM THOMSON.

ON Tuesday last the vote in the Supplementary Estimates amounting to £67,163, being England's share of the purchase money for the extinct Submarine Telegraph Company's property, was passed in Committee of the House of Commons after some rather severe criticism at the hands of Mr. HENNIKER HEATON, Sir G. CAMPBELL, and Mr. LABOUCHERE. Considering that the investment will probably yield a profit of £15,000 or £20,000 a year, these criticisms seem to us a little overstrained. It is true that the sale was not compulsory in the technical sense of the word; but as the Company were precluded from selling to anybody except the actual purchasers, and were forced to wind up their business, it is plain that the sale was compulsory in the sense of not being voluntary, the alternative being that of making the country a present of plant and buildings worth at least £60,000. One other alternative there was which critics like *The Times* and Mr. HENNIKER HEATON entirely lose sight of—the Company might have taken up its cables, stuck to its central office, and sold its repairing ship. Had they done this, which they were certainly entitled to do, the Governments would have been hard put to it, and the telegraphing public seriously inconvenienced. Both parties, therefore, at length agreed to what may be fairly called a compromise. If either of them has reason to complain it is certainly not the purchasing party.

WE describe elsewhere some interesting modifications which have been introduced by Prof. ELIHU THOMSON into the type of oscillating meter first designed by Mr. TAVERNER (extracts from whose patent, No. 123, 1884, will be found in our issue of December 16th, 1887; see also *Electrician*, May 25th, 1888, p. 70). The object of Prof. THOMSON'S device is to render the indications of the instrument directly proportional to the current. We believe, however, that Mr. TAVERNER has succeeded in accomplishing the same thing by more simple means.

THE report of the Electric Lighting Committee of the Bedford Town Council is, upon the whole, a business-like and satisfactory document. The practical and financial success of the Thomson-Houston station at Taunton seems to have created a strong impression upon the minds of the Bedford Committee; though, in preference to leaving the work in private hands, they recommend the Council to establish a station on their own account. In the scheme submitted it is proposed to replace 228 gas lamps by 100 arcs of 1,200 candle-power, and to provide for 4,500 incandescents for private lighting. Upon the basis of an average income of 10s. per lamp from the latter source the Committee hopes to effect a net saving of £345 per annum over the present cost of lighting the streets. The estimates furnished are scarcely in sufficient detail to permit of useful criticism, but they are probably not very wide of the mark—they are certainly much more reasonable than some others which it has fallen to our lot to notice. Nevertheless, some of the minor items are clearly under-estimated. In the capital account we find the entry: "Wire (7 miles), £434." This being the only entry for conductors, it presumably includes the incandescent network as well as the arc circuits; and since it does not appear that any kind of transformer system is contemplated, the figure is certainly much too low. It is true that the arc-lighting circuits are to be overhead, but these alone will cost at least £150 without posts, whilst the low-tension circuit will probably cost considerably more than this *per mile*. Another item to which we are bound to take exception is that of salaries and wages, which is put down for £450 per annum. This sum would barely pay the wages of engine-drivers, stokers, lamp trimmers, and lineman (except

Digitized by Google

the last, two of each class would be wanted), and nothing is left for the electrician in charge. For a station of this order it would certainly be far cheaper in the long run to get a competent man, and to pay him a salary of, say, £250 per annum. When these corrections are made, possibly it will be found that the greater part of the anticipated saving will have vanished; but even so Bedford may well be congratulated on the wisdom of the policy which its Councillors have in contemplation.

In his interesting Paper, "On the Street and Railway Traffic of the Metropolis," recently read before the Society of Arts, Mr. J. Stephen Jeans, while paying the conventional tribute to the possibilities of electricity as a future source of motive power, is apparently somewhat diffident of its present capabilities in this direction. After showing in the most conclusive manner the urgent necessity of relieving our overcrowded streets, Mr. Jeans suggests, amongst other remedies, the establishment of a system of overhead railways, remarking that "there are strong objections to the increase of underground ways of communication." On this point there can, of course, be little difference of opinion, if we are to assume that the present method of working the Underground Railway is to be persisted in for all time. But it is on the very ground that the employment of electricity would reduce vibration to a minimum, owing to the absence of heavy reciprocating parts, and would render the atmosphere of the tunnels somewhat more breathable, that electricians are sanguine that in the adoption of electric traction lies one of the most hopeful solutions of the municipal rapid transit problem as it presents itself in this city. With the Inner Circle worked by electricity, and with the principal points on opposite sides joined by electric subway railways, such as the one now before the House of Commons, we fail to see what objections could be urged against underground railways which would not apply with tenfold force against any system of overhead lines. If the present possibilities of electric traction were more carefully considered, and if the future was left to take care of itself, we think it would be all the better both for electric traction and the public generally. We regret to notice in this relation that the Select Committee of the House of Commons yesterday threw out the London Central Subway Railway Bill, which sought powers to connect Piccadilly with Holborn Circus by means of an underground railway.

King, Brown and Co. *v.* Anglo-American Brush Corporation. This case again came before the Scotch Courts on Wednesday last, and the proceedings will be reported in our next issue.

Obituary.—*Indian Engineering* announces the death at Darjeeling of Mr. W. P. Johnston, Government Electrician of Calcutta, a distinguished officer in the scientific branch of the Telegraph Department.

Sunderland.—The Town Clerk of Sunderland has received formal notice from the Sunderland and District Electricity Supply Company of the intention of the Company to apply to the Board of Trade for a Provisional Order.

Greenwich.—The Greenwich Board of Works have affixed their seal to an agreement between the Board and the London Electric Supply Corporation (Limited), whereby permission is accorded for the laying down of three-inch mains at Deptford.

The Seel Lamp.—According to the *Bulletin des Adjudications*, both the Edison Company and Messrs. Siemens and Halske have commenced legal proceedings against the company which was started in Germany to work the Seel incandescent lamp patents, and claim heavy damages.

Extension of Electric Lighting at Blackpool.—The Blackpool Corporation have decided to extend the electric lighting on the beach from the South Pier almost to the bottom of South Shore. The contract has been awarded to Mr. Thomas Barton, of Ainsworth-street, Blackburn.

Volta's House.—The cottage in the little village of Lazzate, in which Alessandrio Volta spent the summer and autumn months of many years, pursuing the investigations which resulted in the discovery of the voltaic pile, has been secured as public property, and is now adorned with a tablet bearing an inscription.

Woodward Storage Battery.—A correspondent, writing from the States, says:—"The American Company, owing to increased demand for the Woodward plate, have enlarged their works at Detroit, and have now facilities for turning out 1,000 complete cells per day. A company is in formation at Toronto to work the Canadian patent."

Burton-on-Trent.—The Gas Committee of the Burton-on-Trent Town Council recommended, at the last meeting, that the Gas Manager should be instructed to obtain plans and specifications with a view to the introduction of an installation of electric light, for the purpose, if found advisable, of lighting a portion of the borough by electricity.

Tramway between Brookwood and Bisley Common.—The South-Western Railway Company is about to construct a tramway from Brookwood Station to Bisley Common, the site of the "new Wimbledon." The tramway will be about one mile long, and it is to be hoped that the company will not overlook the suitability of electric traction for such a line as this.

A 100 Horse-Power "Otto" Gas Engine.—We learn that Messrs. Crossley Brothers have just finished the second of a pair of double-cylinder engines of 100 horse-power for a large paper works at Godalming. These engines, which are, we believe, the largest ever yet made to be driven by gas, are guaranteed to work with a consumption of 1½lb. of coal per horse-power per hour.

Dundee.—Mr. W. Ogilvy Dalgleish, of Errol Park, has given the committee of the Albert Institute the sum of £1,000 to enable them to extend the electric light to the lending and reference libraries. These rooms are very crowded at night, and the introduction of the electric light is an improvement which the committee had long desired, but were unable to carry out owing to want of funds.

The Claude Telegraph Apparatus.—After eight months' trial, the Paris-Lyons and Mediterranean Railway Company has decided to definitively adopt the Claude apparatus. The towns at present served by this instrument are Paris, Moret, Laroche, Les Laumes, Dijon, Persigny, Chagny, Châlon, Mâcon, Lyon-Vaise, Lyon-Perache. The line is 511 kilometres in length, and the wire used is 3 millimetres in diameter.

Soirée of the Architects' Association.—At the recent *soirée* of the Architects' Association gas could not be used for the footlights owing to insurance. The difficulty was, however, overcome by lighting the stage with incandescent lamps run off accumulators, an adjustable resistance being inserted in circuit so that the brilliancy of the lamps could be varied as desired. This installation was undertaken by the Acme Electric Works.

Ship Lighting.—We learn that Messrs. Paterson and Cooper have recently fitted with the electric light the screw steamers "Islander," "Curfew," "Ardle," "Dundee," "Cambria," "Pladda," "Dean," and "Modjeska." They have also fitted the steam yacht "Tighramara," belonging to Mr. Allan, of the Allan line of steamers, accumulators being in this case employed. The firm has several additional ship installations on hand.

Institute of Electrical Engineers—Students' Meeting.—At a meeting held on Friday, May 17, Mr. Sydney Evershed, A.I.E.E., in the chair, a Note was read by Mr. R. W. Paul, on "Increasing the Fog-Penetrating Power of the Arc Light,"

Digitized by Google

and a Note by Mr. J. N. Cooper, on "Equipotential Surfaces." A discussion followed, in which Messrs. Yeaman, Horn, and the Chairman took part. A vote of thanks to Mr. Evershed closed the proceedings.

Folkestone.—The Folkestone Town Council have decided to support Messrs. Crompton and Co. in an application for a License to supply the electric light to private consumers, and, with a view to lighting the public thoroughfares with the electric light, have given the Gas Company notice of termination of contract. Messrs. Crompton purpose to commence to supply the light in August next, and the contract with the Gas Company terminates in July next year.

Underground Telegraph Line between Washington and Boston.—The Spaulding Telegraph Company are engaged in running an underground telegraph line between Washington and Boston, with branch lines to Baltimore, Philadelphia and New York. The cables, 75 to 160 in number, will be placed one foot under the ground in iron pipes 6in. in diameter. It is anticipated that this service will be less liable to interruption than the overhead one.

The London Central Subway Bill.—On Wednesday last Sir Frederick Bramwell was called as a witness before Mr. Woodall's Select Committee on the London Central Subway Bill. Sir Frederick Bramwell opposed the Bill on the ground that the route was not well selected, and that the electrical plant estimated for by the promoters would be insufficient, and that if adequately increased the working expenses would in consequence be greater than anticipated.

Weybridge.—For the last few nights a small number of incandescent lamps of various candle-power have been lighted in the streets of Weybridge, in order to give the lighting inspectors and others interested in the proposed lighting scheme an opportunity of forming an opinion as to the suitability of these lamps for outdoor purposes. The current was supplied from the dynamo at "Moorcroft," Mr. J. B. Verity's residence, and the light gave general satisfaction.

Glass Tube Conduits.—Experiments are being made on the Continent with a novel form of conduit for underground mains. The conduit consists of a glass tube, protected by a thin coating of specially prepared cement, and enclosed in a cast-iron pipe, the iron being run on hot. Bare conductors can then be used, and it is asserted that not only is the insulation very high but that the conduit is cheap and perfectly air-tight. How the difference between the coefficient of expansion of glass and iron is accounted for we are at a loss to understand.

Lighthouse Illuminants.—Ever since the Trinity House report on the South Foreland tests of lighthouses illuminants was published, an agitation has been carried on by those interested with a view to reopening the question then supposed to have been finally settled. The result of this agitation has been that a committee of the Royal Society, composed of the President, Prof. Stokes, Sir William Groves, and Lord Rayleigh, has been appointed to decide whether the conclusions of the Trinity House are justified by the results of the experiments made.

Franco-Italian-Swiss Telegraph Convention.—The French Italian, and Swiss Governments have agreed to consider their agreements of 1880 as always in force. By the arrangement then concluded it was agreed that whenever the ordinary telegraph lines between any two countries were interrupted messages should be allowed to pass over the lines of the third country without payment. This arrangement applied to telegrams to Corsica and Sardinia, with the reservation that gratuitous transmission was only to last for six months at the most.

The Electric Light in the South African Gold Mines.—The mine and stamps of the Robinson Gold Mine (Transvaal) are lighted by the electric light. When one considers that the £1 shares of this company have recently stood at £60 each, and that the chairman estimates a net profit of £1,620,000 per annum, whereas the total capital of the company is at present but £50,000, the shareholders can hardly consider the installation as an extravagant piece of expenditure. On the other hand, since the electric light has been introduced the mine has, we understand, been worked night and day with a corresponding large increase in output and profit.

A Safe Method of Transporting Sulphuric Acid.—Herr Bickmann has patented in Germany a process for enabling sulphuric acid for manufacturing purposes to be safely transported. He takes advantage of a property of certain salts—of which alkaline sulphates are representatives—by which they give up their water of crystallization when heated and take it up again when cool; and he does so by mixing these salts in an *anhydrous* condition with a calculated quantity of sulphuric acid. The whole mass becomes granular, or may be formed into cakes; and when heated the whole liquefies and may be used as if it were sulphuric acid, for the presence of bisulphate of soda does no harm.

Another Electric Railway Proposed.—On the invitation of some of the leading gentlemen in Brechin, Mr. A. R. Bennett addressed a public meeting in that town on May 16 on the subject of electric railways, and more especially in connection with a proposed line from Brechin to Edgell, a distance of six miles. There was a large attendance, and the meeting resulted in the appointment of a committee consisting of Provost Mitchell; Mr. Shiel, factor to the Earl of Dalhousie; Mr. Lamb, manufacturer; Mr. Valentine; Mr. Anderson and Mr. Philip, Bank of Scotland, to procure estimates and approach the proprietors whose land is required, with a view of avoiding, if possible, the necessity of an Act of Parliament.

Electrolytic Assay of Copper.—In estimating copper electrolytically, Herr F. Rüdorff says:—"It is advantageous to acidify the solution with nitric acid; but when chlorides are present considerable time is taken up in evaporating the solution with sulphuric acid. He found that when an ammoniacal copper solution is electrolised the metal separates in a spongy condition, but that if 2 to 3 grams of ammonia or potassium nitrate be added, and then about 10 cc. of ammonia for every 100 cc. of the solution containing 0·1—0·3 grams of metal, the latter separates in excellent condition, even when the strength of current enployed varies between considerable limits. The operation is at an end when the solution has become colourless."

The Telephone in Spain.—We reproduce from the *Anales de la Electricidad* of Barcelona the following list of telephone exchanges at present in operation in Spain, namely, Alcoy, Alicante, Barcelona, Bilbao, Cadiz, Carthagena, Cordova, Corunna, Felanitx, Gijon, Madrid, Malaga, Murcia, Oviedo, Sabadella, Sebastian, Segovia, Seville, Valencia, Valladolid, and Saragossa. These 21 exchanges have a total of 4,585 subscribers, or an average of 218 each. Madrid heads the list with 1,458, Barcelona comes next with 774, while St. Sebastian comes last with the modest number of seven subscribers. The following towns will shortly be provided with telephone exchanges:—Almeria, Castellon, Grenada, Xerez, Linares, Manresa, Palma, Santander, and Vigo.

The Purchase of the Submarine Telegraph Company's Cables, &c.—In the House of Commons on Tuesday the vote was agreed to, amounting to £67,163, for the acquisition of the Submarine Telegraph Company's property. For the two cables between England and Belgium £9,900 was required, and for the four cables between England and France, including one between France and Jersey, £18,400. Part of these sums would be recovered from France and Belgium, who are partners in the transaction, as appropriation in aid, so that £14,150 would be contributed. A sum of £24,679 was to be paid for the 80 years' lease of the building in Throgmorton-avenue, £9,542 for apparatus, £9,570 for the cable ship "Lady Carmichael," and £5,500 awarded as bonus to retiring officers of the company.

Opening of a Telephone Exchange at Berwick.—On Monday, the 6th inst., a number of business men and others met at the offices of the Northern District Telephone Company, in Woolmarket, for the purpose of formally opening a telephone exchange there. Mr. C. B. Clay, manager of the company, after describing the working of the telephone, with practical illustrations, alluded to the growth of the company's system as compared with that of the Post Office. During the period in which the Northern District Company had added 130 subscribers to

Digitized by Google

their system the Post Office total had been reduced by two. At present the Post Office had 1,300 subscribers, and the company 13,000. Mr. Darling (county Alderman) then declared the exchange open for business. The subscribers to the Berwick exchange are at present 18 in number.

Portsmouth.—On Monday afternoon last a private meeting was held at Portsmouth for the purpose of discussing a proposal for the introduction of the electric light. Mr. R. W. Ford, in the course of some introductory remarks, said the light had already been adopted successfully at Eastbourne, Brighton, Kensington, and other places, and a proposal had been submitted on behalf of the House-to-House Company to establish at Portsmouth a station for supplying the light throughout the borough. The opinion in favour of the light was unanimous, though some of those present thought that the undertaking should be entirely in the hands of the Corporation. It was stated that a company would be started with a capital of £50,000, of which about one-half only would now be called up.

Submarine Telegrams.—In the House of Commons on Friday last Mr. Goschen, in answer to Mr. Henniker Heaton, stated that about £16,000 was expended during the year ended March 31, 1889, on submarine telegrams from England to foreign parts by the various Government departments. Last year's votes showed that the amount paid by the British Government for telegraph cable subsidies was £49,000. He understood that the Eastern Extension Company had laid two cables to Australia. The one which was laid first was unsubsidised, but the Australian Colonies pay an annual subsidy of £32,400 for the second. No contribution was made from Imperial finances. He could not say that he was prepared to consider the advisability of appointing a Commission to consider and report on the whole question of telegraphic communication between England and the various parts of the empire.

The Association of Agricultural Engineers of Great Britain and the Paris Exhibition.—The following circular has been issued by the above association :—

The Associated Agricultural Engineers in Great Britain having resolved not to exhibit their machinery at the forthcoming Paris Exhibition, we feel it our duty, in announcing the fact to our friends and business connections, to state briefly the reasons which have prompted this decision. It is well known that it has been our general practice to take part in all the great Exhibitions throughout the world since their commencement in London in 1851, and, as a body, we have spent more upon such Exhibitions than any other class of manufacturers. It is not merely a question of expense which causes us to refrain from taking part in the Paris Exhibition, but the conditions and regulations of the French Executive Committee under which we were invited to exhibit were of such a nature as would not permit us to do justice to ourselves or to the branches of engineering industry we represent. The facilities for exhibiting offered us were in our judgment totally inadequate, and left us no option but to decline sending our machinery. The names of the firms who have adopted this resolution are as follows :—

The Albion Ironworks Co.
Barford and Perkins.
Barrows and Co.
Bentall and Co.
Bristol Waggon Co. (Limited).
Burlingham, Innes and Co.
Clayton and Shuttleworth.
Coleman and Morton.
Cooke and Sons.
Corbett, Thomas.
Crosskill and Sons.
Foster and Co. (Limited).
Fowler and Co. (Limited).
Garrett and Sons.
Gibbons and Robinson.
Holmes and Sons.
Hornsby and Sons (Limited).
Howard, J. and F.
Humphries, E.
Hunt, R., and Co.
Jeffrey and Blackstone.
Keyworth, J. and H., and Co.
Lister and Co.
McLaren, J. and H.
Maldon Ironworks Company (Limited).
Marshall, Sons and Co. (Ltd.)
Nalder and Nalder (Limited).
Nicholson, W. N., and Son.
Page and Co. (Limited).
Penney and Co.
Picksley, Sims and Co. (Ltd.)
Rainforth and Son.
Ransomes, Sims, and Jefferies (Limited).
Richmond and Chandler.
Robey and Co.
Ruston, Proctor and Co.
Savage, F.
Turner, E. R. and F.

An Electric Wagonnette.—At the Kent County Council on Tuesday, Mr. Links, of Kent House, Sydenham, made application for permission to run a wagonnette propelled by stored electricity over the roads in Kent. The applicant stated that the vehicle would not differ in appearance from carriages drawn by horses, and it would weigh half-a-ton. He would take out an Excise license for the vehicle. The Clerk to the Council stated that the vehicle would have to be licensed under the Locomotives Act, and the Council would not prohibit its use. By the provisions of the Locomotives Act the license would be required to hire a man to walk in front of the carriage with a red flag. He then can "travel" about three miles an hour, a leisurely mode of progression which would enable him to examine the country thoroughly. If he should "travel" at a greater speed he becomes amenable to the law, and liable to heavy penalties.

The Proposed Telephone Convention.—The following circular has been issued by the Committee of the forthcoming Telephone Convention :—

"Dear Sir : A Telephone Convention for the interchange of views on practical telephone work has been organised by the representatives of the Telephone Companies and the Post Office. It will be held in London on the 11th, 12th, and 13th of July next.

"The Committee are of opinion that the success of the Convention will be enhanced by the presence of those engaged in the manufacture of apparatus and appliances used in connection with telephone work.

"The Committee hope that it will be convenient to you to attend.

"In connection with the Convention it is proposed to hold an exhibition of apparatus and appliances. Should you desire to exhibit, the Committee will be obliged by your communicating with the Acting-Secretary, Dr. Julius Maier, 23, Melrose-gardens, West Kensington Park, W., stating the nature of your proposed exhibit, so that the necessary arrangements may be made.—Yours faithfully,

"Julius Maier."

The following are the members of the Committee :—Mr. James Brand, Colonel Jackson, Messrs. W. H. Preece, C. W. Fitzgerald, Owen Unwin, T. Fletcher, J. E. Kingsbury, and Dr. J. Maier.

Birmingham Electric Lighting.—The *Birmingham Daily Post* has the following :—"At the commencement of the present year the Birmingham Town Council were occupied in the consideration of a report of the General Purposes Committee upon the application of Messrs. Chamberlain and Hookham for a Provisional Order to authorise a scheme of public and private electric lighting. The promoters of the Order sought to obtain a concession of the entire city, but the General Purposes Committee could not see their way to consent to this, and sought to limit the Order to a restricted area, composed principally of Market Hall Ward. They also desired that the promoters should be required to form a company with at least £50,000 capital—a sum to which the promoters would only consent if the entire area of the city was included in the Order. Upon the Council adopting the recommendations of the committee, it was generally understood that the promoters regarded their requirements as placing insuperable difficulties in the way of the scheme, and that the latter was therefore abandoned. We are glad, however, to learn that the scheme is still in existence, and that there is a reasonable probability of its being carried into effect. Messrs. Chamberlain and Hookham have not withdrawn from the promotion of their Order, which, after various communications with the Board of Trade and the General Purposes Committee, has practically arrived at its final form. The Board of Trade consider the area suggested by the Corporation a reasonable one, and they have also set down the capital to be provided at £50,000. The committee have submitted that this amount ought to be £100,000, but, not wishing to give any colour to the idea that they desire to hinder the adoption of electric lighting in the city, they have, acting under the authority given to them by the Council, consented that the Provisional Order shall stipulate for £50,000 only. They have also given way upon some matters of working detail, and on Monday, at a fully attended meeting of the committee, approval was given to the draft order as amended by the Board of Trade. It now remains to be seen whether Messrs. Hookham and Chamberlain will take up the Order under its present conditions. There is reason to believe that they will do so, especially in view of the fact that if the Order as now offered by the Board of Trade is not accepted some other promoters will find everything ready to their hand if next year they should be prepared to give notice to obtain an Order in the same terms."

REPORT OF MAJOR MARINDIN ON THE BOARD OF TRADE INQUIRY INTO THE LONDON PROVISIONAL ORDERS.

The following is the text of Major Marindin's report:—

Railway Department, Board of Trade,
1, Whitehall, London, S.W., 9th May, 1889.

SIR: I have the honour to report, for the information of the Board of Trade, that in compliance with the instructions contained in the Order of the 14th March, 1889, under the Electric Lighting Acts of 1882 and 1888, I have held an inquiry in reference to the applications under the said Acts for the following Provisional Orders and Licenses, viz.:—

Title of Order.	Name of Promoters.
Belgravia Electric Lighting Order.	Chelsea Electricity Supply Co. (Lim.)
House-to-House Electric Light Supply Order.	House-to-House Electric Light Supply Co. (Limited).
Kensington and Knightsbridge Electric Lighting Order.	Kensington and Knightsbridge Electric Lighting Co. (Limited).
London Electric Supply Corporation Electric Lighting Order.	London Electric Supply Corporation (Limited).
Metropolitan Electric Supply Co. (Mid-London) Lighting Order.	Metropolitan Electric Supply Co. (Limited).
Metropolitan Electric Supply Co. (North London) Lighting Order.	Do. do.
Metropolitan Electric Supply Co. (South London) Lighting Order.	Do. do.
Metropolitan Electric Supply Co. (West London) Lighting Order.	Do. do.
Notting Hill Electric Lighting Order.	Notting Hill Electric Lighting Co. (Limited).
Paddington Electric Lighting Order.	Electrical Power Storage Co. (Lim.).
St. Martin's and Strand Electric Lighting Order.	Electrical Power Storage Co. (Limited).
South Kensington Electric Lighting Order.	Chelsea Electricity Supply Co. (Limited).
Westminster Electric Lighting Order.	Westminster Electric Supply Corporation (Limited).

Title of License.	Name of Promoters.
South Kensington Electric Lighting License.	Chelsea Electricity Supply Co. (Limited).
House-to-House Electric Supply License.	House-to-House Electric Light Supply Co. (Limited).

The North London Order of the Metropolitan Electric Supply Company was abandoned, and others of the Orders were considerably modified as to areas during the course of the inquiry.

In addition to the above applications, I was upon March 29, 1889, ordered to include in the inquiry and to report upon a Bill promoted by the Metropolitan Electric Supply Company (Limited), and entitled, "A Bill for authorising the Metropolitan Electric Supply Company (Limited) to erect and maintain Electric Lights and Works, and to supply Electricity within the Parishes of St. James's, Westminster, and St. Martin-in-the-Fields, in the County of Middlesex, and certain other Parts of the Metropolis, and for other Purposes."

The inquiry was held in the Town Hall, Westminster, was opened upon Wednesday, April 3, and was concluded upon Wednesday, May 1, the sittings having actually occupied 18 days. I also devoted the whole or part of three days in inspections of the works, and proposed sites for works, belonging to the different companies.

I have had during the inquiry the valuable assistance of Major Cardew, R.E., the Inspector of the Board of Trade for Electricity, who has advised me upon all scientific and technical details.

[The report next proceeds to furnish full details respecting the various Orders and Licenses. This information has, however, already appeared in our columns; we therefore omit it for the present in order to find room for the more material portion. We hope, however, to reprint this section of the report for convenience of reference in a succeeding issue.]

SYSTEMS OF SUPPLY.

Inasmuch as the several companies applying for Orders are for the present more or less committed to the supply of electricity by one or other of several different systems, although they would be by the terms of the proposed Orders actually bound to no system in particular, and would no doubt at some future time be driven to adopt whichever might be found to be the best, it is necessary to consider first the relative advantages and disadvantages of the different proposed modes of supply.

This question was the one which was most keenly contested at the inquiry, and the great bulk of the evidence was directed far more to the attack and defence of the rival systems than to the question of competition, or to the size of area, which, however, should depend greatly upon the system used.

The systems proposed are:—

1. The supply by means of high pressure alternating currents and transformers, which system may be subdivided into two heads, viz.:

(*a*) The system adopted by the London Company, viz., the supply from one large generating riverside station outside the crowded districts of the Metropolis, with trunk mains carrying the currents at the unprecedentedly high pressure of 10,000 volts, to transforming stations inside or near to the area of supply, whence the current will be taken in distributing mains, with a pressure of 2,500 volts, to the consumer's premises, or to secondary distributing stations, there again to be transformed to a pressure of 100 or 50 volts;

(*b*) The system adopted by the Metropolitan and House-to-House Companies, viz., the supply from a number of generating stations in or near to the area of supply, with distributing mains carrying the current at a pressure of from 2,000 to 1,000 volts to the consumer's premises, or to distributing stations, where, as in the case of the London system, it will be transformed to a pressure of 100 or 50 volts.

2. The direct supply by means of continuous currents, which may be dealt with under three heads:—

(*a*) The system adopted by the Chelsea Company, viz., the use of one generating station for a considerable area, and the charging with a pressure of from 1,000 to 2,000 volts several accumulator stations, with duplicate sets of batteries, at different points within the area of supply. The supply mains leading from these accumulator or distributing stations will carry current directly into the consumer's premises at a pressure of 100 volts, the supply being entirely from accumulators. The charging and discharging of the same set of accumulators cannot be carried on at one and the same time, so that it will be necessary to charge the batteries during the hours when there is little or no demand for current.

By the use of additional mains it would be possible to supply direct from dynamos at the generating stations when not charging, but it is proposed for the present to furnish the whole supply from accumulators. One set of these is charged at a time, the other set in the meantime meeting whatever demand there may be. The shifting over of the batteries from charging to supplying is effected by an automatic arrangement.

(*b*) The system adopted by the Kensington and Knightsbridge Company, which is at the present moment supplying partly by accumulators and partly by dynamos, the former doing the whole work during the hours of minimum supply, and the latter being employed in charging the batteries, and supplementing the direct supply from the batteries during the hours of maximum supply. This system, which other companies, viz., the Notting Hill Company and the Westminster Company, propose to adopt, would in a large area require several generating stations.

(*c*) The system adopted by the St. James and Pall Mall Company, which has commenced to supply under the terms of a License in the parish of St. James's. This is the simple direct system at low pressure, without any accumulators, and according to the evidence it is useful only for small areas with a radius not exceeding half a mile.

This system would therefore require a very large number of generating stations if adopted for large areas.

The relative advantages and disadvantages of the high-pressure transformer system and of the direct system as used by the Chelsea Company are thus concisely stated by Major Cardew, who bases his remarks upon the evidence given at the inquiry:—

"The transformer system carries the high pressure up to the houses. The distributing mains, therefore, are of small size. A large district can be served from one station, and the regulation of pressure in the distributing mains can be very good. There should be no great difficulty in maintaining a standard pressure within a variation of 2 per cent. The pressure in the houses may be different in different cases, according to the needs or fancy of the consumer.

"It is also a simple system to work, and the dynamos are simple, and can be made in easily replaceable parts.

"On the other hand, the high pressure necessitates great care and expense in insulation; the conveying of this high pressure to, at any rate, one point on the consumer's premises, and the risk of a contact between this circuit and the low-pressure circuit inside the house, involves some risk to life, although it may be reduced to a minimum by proper regulations and precautions; the main cannot be handled or connections made when the pressure is on; the re-

Digitized by Google

gulation in the houses is not so good as in the mains, as the transformers act as a considerable added resistance, and cause an increased variation of pressure in the power as compared with that in the mains; the system cannot at present be efficiently utilised for motive power, or for electric deposition or other chemical uses, such as charging accumulators; and it is very doubtful whether a practically successful alternating motor is likely to be brought out; the system depends entirely on running machinery, and engines and dynamos have to be kept in motion throughout the 24 hours; the general efficiency must be low when the supply is near its minimum, a condition which, so long as it is utilised for lighting alone, obtains during about 18 hours of every day on the average, and a serious accident in the generating station might stop the supply for a considerable time. Alternating machines cannot be so readily connected together to run in parallel circuit as continuous current machines. The measurement of alternating current, pressure, and power also offers considerable difficulty, and the available instruments and methods are far more restricted in number than is the case with the corresponding quantities in continuous supply.

"The Chelsea system has the advantage of high pressure between the generating and distributing stations, without its being brought into the consumer's premises, and the distributing stations may be so numerous that each one serves only a small district, and in this way the size of distributing mains may be kept down; the supply from batteries has these enormous advantages: that in the event of a total breakdown at the generating station supply can still be maintained for some hours; that it is not necessary to keep the machinery at the generating station in motion throughout the whole 24 hours, and that the batteries provide a supply for the long hours when very little is required; the system has the advantages of continuous currents, viz., applicability to the supply of motive power, and other uses besides light and heat, and greater ease of measurement. The regulation, with small areas supplied from each substation, should be very good, and there is no doubt that a battery current is less destructive to lamps than one supplied from dynamos, whether alternating or continuous.

"On the other hand, the cost of the batteries is very great, and also that of the skilled attention they require, while their efficiency at maximum output is probably rather low; the automatic switches are a weak point, and any failure in this action would probably ruin the batteries at that station; the insulation of large batteries cannot be maintained at all high, and the numerous joints, in the presence of acid fumes, are a source of weakness.

"This system, in which the supply is entirely from accumulators, if it can be successfully worked in practice, possesses very great advantages. Unfortunately it cannot be forgotten that identically the same system was tried a few years ago at Colchester, and ended in disastrous failure."

The principal objections which have been urged against the London Company's scheme specially are as follows:—

(*a.*) That having only one generating station an accident might stop the whole supply.

That an accident, such as the bursting of one of the large steam-pipes, might have this effect is certain, for even if it did not kill or injure those in charge of the machines it would fill the whole building with steam, which would greatly impede, if it did not entirely prevent, the necessary work of the station from being for some minutes carried on, and would, I am advised, by condensing on the dynamos, switches, &c., working at very high pressure, possibly cause an electrical breakdown. The risk of such an accident, or any serious accident to the running machinery, might no doubt be provided against by a proper system of inspection and testing, and so far as the filling of the building with steam, and risk to life from the bursting of a steam-pipe, is concerned, the ill effects might be minimised by covering in the pipes, but the result of any cessation of work for even a few minutes at a generating station, upon which the supply of a very large area is solely dependent, would be so serious that I consider that it will be necessary to require that the company shall, to the satisfaction of the Board of Trade, so subdivide the station at Deptford as practically to provide two distinct generating stations, or shall forthwith establish a second generating station in some other locality. In either case there should be duplicate sets of mains led by different routes to each of the distributing stations in the area of supply.

(*b.*) That the great length of the trunk main increases the chance of a breakdown, and that the pattern of main proposed, with its numerous joints, is unsatisfactory.

This is a question which, no doubt, merits the serious attention of the Board of Trade, but it is one which I have no reason to believe would not be satisfactorily dealt with by proper regulations.

(*c.*) That the proposed pressure of 10,000 volts is so enormously in excess of anything which has hitherto been worked with that the scheme is a gigantic experiment.

No doubt in a certain sense this is true, but it must not be forgotten that whereas a few years ago the pressure of some 200 volts was considered to be the limit of safety, this Company has for some time been working, safely and successfully, at a pressure of more than ten times this amount, and as the so-called experiment of still further raising the limit of pressure would, if successfully carried out, be of immense benefit both to the public and electric lighting undertakers, I do not consider that, under proper regulations, the London Company should be prevented from carrying out a scheme in which they have shown the greatest confidence, and which the majority of the scientific witnesses who have been called approve of in principle.

(*d.*) That the telegraphic and telephonic service of the Metropolis will be seriously interfered with.

This difficulty ought to be easily met by proper regulations and proper clauses in the Order.

On the other hand, the system of the London Company possesses the undoubted advantages over any others, which arise from the location of the generating station on the riverside, and the consequent removal from the crowded parts of the Metropolis of all inconvenience from noise, vibration, smoke, and heavy traffic.

It will probably also be found that from the economy resulting from the concentration of plant, the facilities for getting a cheaper supply of coal, and the possession of large storage capacity upon the premises, the cost of production under the London system will be largely reduced, to the eventual benefit of the consumer.

Of the scientific witnesses called as to the relative merits of the two systems of supply the great majority were in favour of the alternating transformer system for large areas

There can, however, be no doubt that from a consumer's point of view, leaving the question of price out of consideration, the supply made by such a company as the Chelsea, viz., from accumulators alone, is the most valuable, and that the supply by means of all the direct systems has this advantage, that it can be utilised for power, which cannot at present, at any rate, be said of the supply given by the transformer system.

It would therefore be wisest, in my opinion, to give fair scope to all the proposed systems, all of which are capable of being worked; and it may be predicted with tolerable certainty that whatever system proves itself to be the best under all circumstances will eventually be adopted by all.

Conclusions.

After a careful consideration of the above points, and of all the evidence and arguments put before me, I have arrived at the following general conclusions:—

(1.) That it must be admitted that the science of electric lighting has now reached the point at which a supply can be made which will be of very great benefit to the public, and that the power of obtaining this supply should be within the reach of all persons who may require it. For this reason it seems to me that although the wishes and opinions of the local authorities in the areas proposed to be supplied should be consulted and deferred to as far as possible, the mere objection by a local authority to the introduction of a company proposing to supply electric light upon general grounds should not be considered sufficient to exclude such company, unless the local authority should express its intention to undertake the supply, and give evidence that it proposes to apply for permission to do so, and this should apply with more force when it can be shown that the exclusion of a company from such an area would injuriously affect the service of other contiguous areas.

(2.) That in dealing with this question it should be considered as one affecting the interests of the Metropolis as a whole, and as an area which at no very distant time may be for purposes of lighting and management of roads and streets under the control of one central authority; and that, therefore, the whole of the Provisional Orders granted for the Metropolitan area should, as far as possible, be identical in form, with identical provisions as to supply, compulsory powers, interference with streets, and more than all, as to price.

In my opinion the scheme adopted in 1883 of dividing the area of supply into two areas (A) and (B) would not be likely to work so much to the advantage of the public as the proposal in most of the Orders under consideration to make the supply compulsory under requisition over the whole area upon equal terms.

I consider, however, that in order to insure that some work shall be at once undertaken in every parish or district within the area of supply under such Order, there should be a list of streets scheduled for compulsory laying of mains, and a deposit made in every case where the local authority may wish to have it.

Where there are two companies in the same area, different streets should be scheduled for each.

With regard to the clauses affecting supply, interference with streets, testing, position of stations and distributing boxes, and other details, the whole of the suggestions made by the local authorities should be carefully weighed, and those which are considered necessary embodied in the model form of Order.

With regard to price, I do not consider that any one district in the Metropolis should be put in a better position than another.

Digitized by Google

Taking the area as a whole, it does not appear that it would be wise to fix a lower maximum than 8d. per unit.

It is true that the London Company is now supplying at 7½d., and the maximum in the St. James and Pall Mall Company's License is 7d., but these companies are competing in an exceptionally good area.

There would, however, appear to be a necessity for a reduction of the high rate for minimum supply—that is, the sum which every customer taking a supply can be call ed upon to pay, irrespective of the amount which he has consumed, and which in the Orders varies between £3. 6s. 8d. per quarter in the case of the Notting Hill Company, and £5. 10s. in the case of the Metropolitan Company's South London Order.

The latter Company has consented in the Mid-London and West London Orders to reduce the minimum to 13s. 4d. per quarter, and I consider that whatever minimum is fair should be adopted throughout.

The provision for revision of price after each seven years, in the agreements between the Metropolitan Company and the Strand and Marylebone local authorities, seems to me to be somewhat contrary to the policy of Parliament when dealing with the Electric Lighting Act. If any such provison be inserted it should be general, and it would appear to be more fair that the revision should take the form of a sliding scale upon the basis of a 10 per cent. dividend, the standard being fixed after the experience gained by the working of the first seven years.

It has been suggested that in the matter of price the consumer should, if he elects himself to pay the whole cost of connecting his house to the mains, have no minimum at all imposed upon him, but although I can see no objection to this proposal such a provision, would hardly be necessary where the minimum is reduced as in the Metropolitan Orders.

(3.) That in every case the supply of electricity, whether by a company or by a local authority, should be under statutory obligations as well as statutory powers by means of a Bill, a Provisional Order, or a License.

(4.) That there is no objection to the granting of a large area of supply to any company which shows that it has sufficient capital and is capable of coping with the demand. On the contrary, a large and rich company is likely to be the best and most economically managed concern, to be able by working over a large and scattered area to develop the demand for the light, and by rapidly increasing its business to be the sooner in a position to reduce the price of the article supplied.

(5.) That in the abstract competition is desirable, as tending to keep down the price, and to cause the manufacture and supply of electricity to be carried on with all the attention and energy which it is possible to devote to it.

The competition with gas, which at present at any rate, and probably for many years to come, will appeal to a totally different class of customer, will not be nearly so effective, while the potential competition from the power of calling in a new company in an area badly served is not likely to be called into play until the bad service has passed through many degrees, and has reached a very low ebb indeed.

The question as to how many companies should be granted concurrent powers in one area requires more consideration.

In cases where the local authority objects to the entrance of any company, and it is decided to overrule the objection, I think that one company only should be granted powers.

In cases where two or more companies have obtained the assent of the local authority, the following facts must not be lost sight of :—

1st. That the laying of the mains of several companies up one street means so much dead capital, and, moreover, the provision of a certain amount of useless material, which the local authority would have to pay for if it should decide to purchase the undertakings after the lapse of 42 years.

2nd. That, no matter what regulations or stipulations may be made as to the laying of mains, the interference with the streets, and the consequent inconvenience to the public, must be in a certain degree proportionate to the number of companies having powers over these streets.

For these reasons I am of opinion that, for the present, powers should not be given to more than two companies over the same area, and, inasmuch as the companies supplying under the alternating current and transformer system cannot supply electric energy capable of use for motors, that both these two companies should not be those using this system.

In order, therefore, to leave room for the entrance of a direct supply company into an area where two alternating current transformer companies have been assented to, it will be necessary to choose one only of these companies, and this will lead to a certain amount of districting.

(6.) That wherever a company now supplying a district by means of overhead wires is granted an Order for such area, it should be placed under the obligation to remove these overhead wires within a period of two years from the granting of the Order ; and, if such a thing be possible, that this company should be prevented from invading a district in which it has not got powers by means of overhead wires.

(7.) That in order to reduce as much as possible the disturbance of streets, clauses should be drafted making it obligatory for companies to lay their mains in existing subways, and to transfer them into subways which may be made in the future upon being called upon to do so.

If possible it would also be advisable to provide that, wherever circumstances admit of it, and where there is no subway, the conduits put down to lay the mains should be made capable of accommodating the mains of both companies in the area, if there be two companies having powers therein.

To a certain extent also it would appear to be right that the local authorities should have the power of objecting to the sites for generating, as distinguished from distributing stations, subject to an appeal to the Board of Trade.

Recommendations.

Applying these principles to the Orders asked for by the several companies, I recommend the Board of Trade to adopt the following course in each case.

I. *The London Electric Supply Corporation.*—As this Company and the Metropolitan Company are competing in many parishes and districts, and are both companies working with alternating currents, unable at the present time to provide for motive power, the areas applied for should be districted, and I propose, therefore, to allot to the London companies and to include in the London Order the following parishes and districts :—

The portion of St. Martin-in-the-Fields lying to the south of the Strand and west of St. Martin's-lane ; the portion of St. Margaret and St. John, Westminster, lying to the north of Victoria-street, excepting that portion of St. Margaret's lying to the west of St. George, Hanover-square ; St. James, Westminster ; St. George, Hanover-square ; Chelsea ; the Greenwich District ; St. Mary, Rotherhithe ; St. Mary, Bermondsey ; the District of St. Olave ; the District of St. Saviour, Christchurch ; and that portion of St. Mary, Lambeth, lying to the north of Westminster Bridge-road.

The only dissenting local authorities in the above areas are the Vestries of St. James, Westminster, of St. Mary, Lambeth, and of St. Margaret and St. John, Westminster, and the District Board of St. Saviour's ; but of these the first two would, judging from the statements of their representatives at the inquiry, consent, if their objections be, in the opinion of the Board of Trade, fairly met ; and it should be pointed out to them that while St. James' would under the terms of the Order gain by the compulsory removal of the overhead wires with which the London Company is at present largely supplying in the parish, it is in the case of St. Mary, Lambeth, essential to the continuity of the London Company's area that this company should have the means of passing through the northern end of the parish.

This last reason applies equally to the parishes of St. Margaret and St. John, and the opposition of the united Vestry of these parishes was not so strong as to lead to the belief that it would object to the division of the parishes as I propose between two companies, especially as there appears to be a demand for electricity in the district.

The district of St. Saviour's, after assenting to the granting of the Order, withdrew the assent, but did not appear at the inquiry to give any reasons for so doing, and as the district intervenes between other portions of the London area, the local authorities of which have assented and wish for the supply of electric light, I submit that the objection of St. Saviour should be overruled.

The case of St. James and St. John, Clerkenwell, is difficult to deal with. This parish is cut off from the district which I propose to allot to the London Company, and the Metropolitan Company has abandoned the North London Order, in which it was included, while the Vestry has assented to the entrance of both companies.

If the City should consent to allot a district to the London Company, giving access to Clerkenwell, this parish should be added to the London area, otherwise it might be suggested to the Metropolitan Company to adhere to their North London Order so far as this parish is concerned.

The general form of the clauses of the Order should be similar to those in the other Orders for the Metropolitan area, and it will be better to deal with all the suggestions and requirements of the local authorities on this head generally, when the principles upon which the Orders are to be granted have been considered and determined ; but there are two special clauses in the London Order, which have already been alluded to, and might be dealt with separately.

I do not see any objection to Clause 55, authorising the supply to a local authority of electricity in bulk, provided, in the opinion of the legal authorities, it be possible to place the local authorities under the obligations of the Order by any such clause.

Digitized by Google

As to Clause 56, I think that, subject to the subdivision of the generating station at Deptford, as recommended on page 19 of this report, it would be a mistake to reduce the cubical dimensions of the building.

A compliance with the recommendations on the above-mentioned page should be a condition upon which the granting of the Order should depend.

II. *The Metropolitan Company.*—To this company I would recommend that the following area should be allotted :—

Under the Mid-London Order.—St. Giles-in-the-Fields; St. George, Bloomsbury; St. Andrew, Holborn above Bars; St. George the Martyr; St. Sepulchre, Saffron-hill; Hatton-garden, Ely Rents and Ely-place; the Liberty of Glasshouse-yard; St. Anne, Soho; St. Paul, Covent-garden; St. John the Baptist, Savoy; or precinct of Savoy; St. Mary-le-Strand; St. Clement Danes and the Liberty of the Rolls, together with the extra parochial places known as the Charter House, Gray's Inn, Lincoln's Inn, Staple Inn, and Furnival's Inn.

The whole of the local authorities in the above area assent to the Order.

Under the West London Order.—St. Marylebone, the Vestry of which assents to the Order.

Under the South London Order.—St. Mary, Lambeth; St. Leonard, Streatham; and Clapham.

Neither of the local authorities affected, viz., the Vestry of St. Mary, Lambeth, and the Wandsworth District Board, has signified its assent, but both would probably do so if their objections be met in a manner considered fair by the Board of Trade.

Under the Bill.—That portion of St. Martin-in-the-Fields which lies to the East of Northumberland-avenue, Charing-cross, and St. Martin's-lane.

The Vestry of St. Martin-in-the-Fields assents to the Bill.

With powers in this area the Metropolitan Company will have access from the main portion of the Strand District to the outlying portions, and will also have powers over some portion of the parish of St. Martin-in-the-Fields, contiguous to their existing station in Whitehall. In the latter portion, although the company will be competing with the London Company, there will not be two alternating-current companies, as the supply from the Whitehall station is by continuous current.

The only area in which there will be two competing alternating-current companies is in North Lambeth, where it cannot well be avoided.

III. *The House-to-House Company.*

IV. *The Notting Hill Company.*—I recommend that the areas as agreed to between these companies and the Vestry of Kensington be approved of, and the Orders granted in suitable terms.

V. *The Kensington and Knightsbridge Company.*—Similarly, in the case of this company, I recommend that the area as agreed to between the company and the Vestry of Kensington be approved of, and the Order granted.

With regard to the part of the parish of St. Margaret, Westminster, applied for, I recommend that the Order be approved of subject to the consent of the Vestry. This body has decided to object to the powers which are being exercised under Licenses granted by consent being extended to those given by Provisional Order, but I trust that the matter may be so represented that this decision may on reconsideration be altered.

VI. *The Chelsea Company. South Kensington Order.*—This Order is assented to by the Vestry of Kensington, and I recommend that it be granted for the area agreed to.

Belgravia Order.—In the case of this Order I see no valid reason for dispensing with the consent of the Vestry, which has been withheld. Consent has been given to the Orders of three other companies.

VII. *The Westminster Company.*—Although the scheme of this company is in a somewhat inchoate condition, the Vestry of St. George's, Hanover-square, has assented to the Order. The Vestry of St. Margaret and St. John, Westminster, withholds consent, but for reasons already given I consider that powers over part of the area asked for in this district should be given, the existing station of the company being in this area.

I recommend that the Order be granted for the parish of St. George, Hanover-square, and the portions of St. Margaret and St. John, Westminster, lying to the south of Victoria-street.

This company has abandoned the remainder of the area originally applied for.

VIII. *The Electrical Power Storage Company. Paddington Order.*—In view of the objection of the Vestry, and its expressed intention to undertake the lighting of the parish, and for other reasons given below, I cannot recommend that this Order be granted.

St. Martin's and Strand Order.—The Vestry of St. Martin's assents, and the Strand District Board dissents to the Order.

The company applying for these Orders is a company manufacturing batteries and other electrical appliances, and it seems more than doubtful whether, under the Articles of Association, there is any power to undertake the manufacture and supply of electricity for house-to-house lighting purposes. However this may be it is perfectly clear from the evidence of the manager of the company that the company does not intend to exercise the powers which would be granted by the Order, but to transfer them to some other persons.

I have no doubt that these persons are perfectly willing and competent to carry out the powers and obligations of the Order, but I submit that it would be quite contrary to practice to grant an Order to any but a properly constituted company, proved to be in a position to act under it, and as this has not been done I cannot recommend that the Order be granted.

It should be understood that in every case the recommendation to grant these Orders is on the understanding that the whole of the works, both at the generating and other stations, and along the mains, are to be planned and executed in a manner such as to satisfy the Board of Trade that the public are properly protected, both as regards safety, and, so far as may be possible, from any extinction of the light for an appreciable time, and that should it be found impracticable to carry out the districting between the London and Metropolitan Companies in the manner which I have proposed, the whole question will be reconsidered, so that the areas may be fairly readjusted.

The Metropolitan Orders for the Strand and Marylebone should be in as nearly as possible the same form as those applying to other parts of the Metropolis, as there does not appear to be any sufficient reason for treating these areas differently from any others.

The only districts applied for in which I have decided not to recommend the granting of Orders, as amended, are the parishes of St. Pancras and Paddington, where the local authorities should, I think, be granted time to decide definitely whether or not to carry out the lighting of their parishes under the powers of a Provisional Order; and the City, which, although not exempted from the operation of the Electric Lighting Acts, is in a somewhat different position from other parts of the Metropolis.

The Commissioners of Sewers, acting for the Corporation, are endeavouring to obtain tenders for the lighting of the City, but I see no reason why the principle that all such lighting should be done under statutory powers and obligations should be departed from in their case.

If the Board of Trade should agree in this view, I would urge the Commissioners of Sewers to consider whether the Orders as remodelled do not sufficiently provide for all their requirements, and in that case to consent to the division of the area of the City between the two competing companies, viz., the London and the Metropolitan Companies, the latter company being allotted the portion nearest to the Strand District, and the former the Central and Eastern portions of the City, so that access may be given to the Parish of Clerkenwell, the Vestry of which wishes for an Order to be granted to this company.

In addition to the above-mentioned Provisional Orders the two Licenses applied for by the Chelsea Company and the House-to-Company have to be considered.

These Licenses are both for areas included in the portions of the parish of Kensington allotted to the companies respectively by the Vestry, and the consent of the Vestry has been given.

Subject to any alterations in clauses which may be found necessary to make the provisions of these Licenses similar to those of the Provisional Orders applied for, I can recommend that, for the purpose of expediting the commencement of the works, they be granted.—I have the honour to be, Sir, your obedient servant,

F. A. MARINDIN, Major, R.E.

I concur with the above report.

P. CARDEW, Major, R.E.

The Secretary, Railway Department, &c., &c.,
Board of Trade.

The Secretary to the Board of Trade has forwarded the following letter to the Chairman of the London County Council :—

"Board of Trade (Railway Department),
"London, S.W., May 18, 1889.

"ELECTRIC LIGHTING ACTS, 1882 AND 1888.

"MY LORD: I am directed by the Board of Trade to transmit to you the enclosed copies of Major Marindin's report, made after his inquiry, held by direction of the Board of Trade, into the various applications for Provisional Orders and Licenses under the above-mentioned Acts in respect of the Metropolis, as well as into the subject-matter of a Bill introduced into the House of Commons by the Metropolitan Electric Supply Company (Limited).

"In forwarding copies of this Report for the consideration of the County Council I am to inform you that, subject to any observations that they may wish to offer, the Board of Trade propose to adopt the recommendations of the Report with regard to the allocation of the various districts to the several companies.

Digitized by Google

"A description of these areas will be found in the Report, from which it will be seen that in the following districts only powers over the same area are proposed to be granted to more than one company, viz. :—St. George's, Hanover-square; a small portion of the parish of Lambeth, to the north of Westminster Bridge-road; a small portion of the parish of St. Martin-in-the-Fields, to the east of Northumberland-avenue and St. Martin's-lane.

"The Board of Trade concur in the opinion expressed by Major Marindin that, looking to the fact that the supply of electricity on the alternating-current and transformer system cannot be made use of for motors, the competition of a system which can be made useful for motors is desirable, and that, consequently, where powers are granted within the same area to two companies, both those companies should not be those using alternating currents. This principle has been adopted in allocating the various districts, except in so far as regards a small portion of the parish of Lambeth to the north of Westminster Bridge-road, which has been allotted to the London Corporation and the Metropolitan Company, both of which propose to use alternating-currents and transformers.

"The latter Company was the only one which proposed to take the whole of the parish, and they are in possession of a site for a generating station in the northern corner of the parish. The whole of the parish was, therefore, allotted to this Company, but it was found necessary also to grant powers to the London Company over a portion of the parish, in order to give access to the districts allotted to it on the other side of the Thames.

"A small portion of the parish of St. Martin-in-the-Fields has been allotted to the same two Companies. But in this instance the latter Company possess a generating station in Whitehall-place, from which the supply is by a continuous current.

"In two of the parishes allotted to the London Company—viz., Chelsea and St. James's, Westminster—powers to supply electricity have already been granted to other companies by Provisional Order and License, granted in the years 1886 and 1888 respectively. Both of these Companies, however, use continuous currents.

"In the present Orders it is proposed to substitute for the provisions as regards Schedule A and Schedule B, hitherto usually adopted, a provision that the undertakers should be bound at once to lay down mains in certain streets to be scheduled, and that they should be compelled to lay mains in any other streets in the area on requisition by owners or occupiers.

"With regard to the question of capital, I am to point out that, while the capital of the various companies would, doubtless, be wholly inadequate if the entire areas allotted to them required to be lighted at once, they possess, in the opinion of the Board of Trade, sufficient capital to provide for all the work they are likely to be called upon at present to perform.

"As regards the maximum price chargeable, the Board of Trade, in the absence of any evidence that such a price would be excessive, propose to adopt the maximum of 8d. per Board of Trade unit. They think, however, that a clause should be inserted providing for a revision of the terms of charge at the end of seven years from the date of the Order, and they propose that this clause shall be so drawn as to make it possible to adopt, as regards electrical lighting, the principle of the sliding scale of charge, which has been applied with advantage under the Gas Acts. It is impossible at present to foresee the initial price which it will, at the end of that period, be reasonable to prescribe; but, following the analogy of gas, and considering that the electric companies only have a certain tenure of 42 years, the Board of Trade are of opinion that a price arranged on the basis of a 10 per cent. dividend would not be unreasonable.

"With a view of saving time the Board of Trade are now going through all the objections raised to the clauses of the Orders, and are preparing a model Order, which, with the necessary variations for the varying circumstances of different districts, would be adopted for the whole of the applications, and that as soon as this model Order is in a sufficiently advanced stage a copy will be forwarded to the County Council.

"In conclusion, I am to state that as time is of the utmost importance the Board of Trade would be glad to be favoured with the observations of the London County Council at their earliest possible convenience.—I have the honour to be, my Lord, your Lordship's obedient servant,

"(Signed) "HENRY G. CALCRAFT.

"The Earl of Rosebery, London County Council, Spring-gardens."

LONDON DISTRICTS AT PRESENT NOT ALLOCATED.

In view of Major Marindin's report on the various electric lighting schemes which came under his consideration during the inquiry instituted by the Board of Trade last month, it may be interesting to note some of the chief London areas which have not yet been allocated.

Madagascar.—The telegraph lines recently established in Madagascar have been almost entirely destroyed by floods.

PROF. ELIHU THOMSON'S OSCILLATING ELECTRIC METER.

Our New York correspondent writes as follows:—"Some months ago Prof. Elihu Thomson, as noted in your columns at the time, brought out an ingenious electric meter in which the indications were effected by the oscillations due to the transfer of a liquid from one bulb to another, by means of the evaporisation caused by a conductor heated by the current and passing through the liquid. Prof. Thomson devised some forms of this apparatus, and I believe that of the standard adopted by him

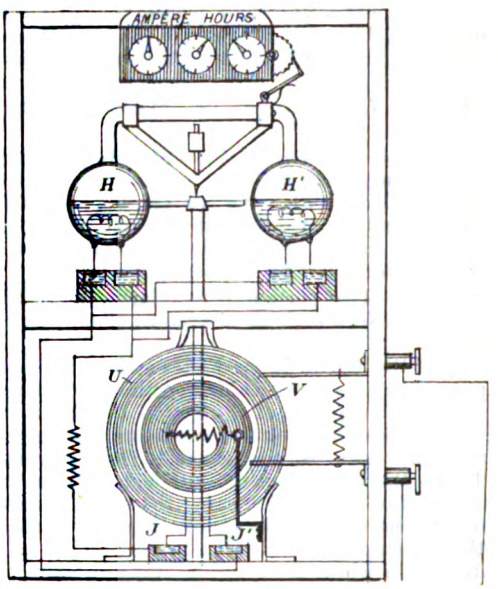

FIG. 1.—Prof. Elihu Thomson's New Oscillating Electric Meter.

several are now in use in various parts of the country on Thomson-Houston circuits with great success. Prof. Thomson has now introduced an interesting modification into the present form of this meter. It is obvious that in the first form described the effect is to produce a vibration which is as the square of the current in the coil, because the heat effect is as

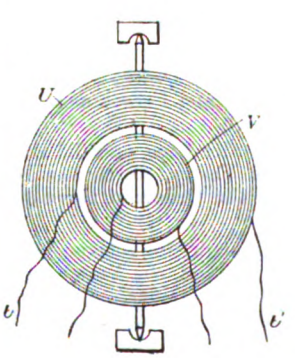

FIG. 2.

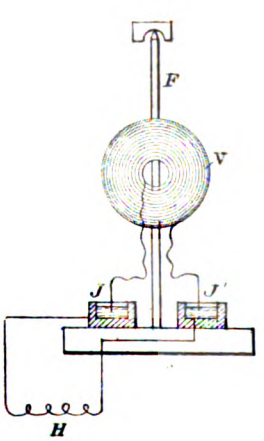

FIG. 3.

the square of the current, and is proportional to the time of flow. The effect principally desired, however, is one proportional not to the square of the current, but in the case of an electric meter directly to the current itself which is to be measured. It is to meet this point so as to produce a registry in direct proportion to the current flowing on the circuit that the new meter has been brought out. The correction is attained by passing currents through the meter in direct proportion to the square roots of the currents in the circuit of the lamps or motors, so that whether one lamp or a dozen are in

Digitized by Google

use the record shall be true. One method of accomplishing this with a fair approximation in the case of alternating currents is to supply the meter from the secondary of a transformer whose primary connects with the circuit carrying current, the same as or proportional to the current to be measured, and to arrange the coils of the transformer so that their inductive relation may change through their mutual re-action or by other means so as to indicate the square roots of current passing. Prof. Thomson has also applied the method to the direct registration of continuous currents." The following description of the instrument appeared in a recent number of the *Electrical World* (New York):—

The general arrangement of this instrument is shown in Fig. 1, and Figs. 2, 3, 4 and 5 show a number of the details. As shown in Fig. 2, U is a fixed coil placed in the circuit with the lamps used by its terminals t t'. Mounted on a vertically-pivoted shaft, delicately poised, is a second coil, V, whose terminals are carried through J J' to the heating coils H or H' of the preceding Fig. 1. The coil V is, however, capable of rotation on its vertical axis F, Fig. 3, and to avoid friction its terminals dip in mercury cups J J', Figs. 3 and 4, from which cups connection is made. A delicate

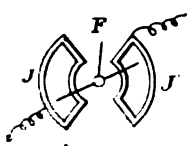

FIG. 4.

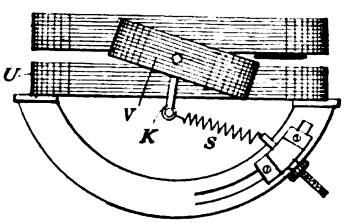

FIG. 5.

spring S, shown in Fig. 5, adjustable as to its fixed extremity both in position and elasticity, is attached to an arm K, extending as shown from the coil V or its supporting axis. The spring S is wound conically and is of very light wire, and is adjusted to pull in such direction, and its elastic force is made such that alternating currents in coils U will, when coil V is circuited through H, Fig. 3, cause deflection of V from the position shown in Fig. 5 to the position at which its plane approaches a right angle with that of coil U, and at the same time that the current induced in coil V by those in U shall be as the square roots of the currents in U. This condition is found to be attainable with tolerable approximation to accuracy by suitably proportioning the restraining influences governing the motion of the coil V under the deflective actions exerted.

The object is evidently to so adjust the parts and their relations of size and effect that the currents induced in coil V by currents in U shall always be in proportion to the square roots of the currents in U. If the coil V did not deflect, the currents in it would be in direct proportion to those in U. The deflection of V, however, causes the desired diminution.

Prof. Thomson has also applied the method to the direct registration of continuous currents. For this purpose a variable shunt V, Fig. 6, or other means of controlling the flow of current to the

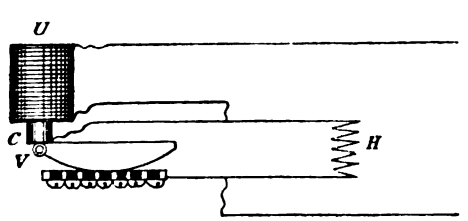

FIG. 6.

lamps, as, for instance, the heating-coil H, is employed. The variable shunt may be operated by a solenoid core C, or other device responsive to the flow of current in the circuit. The arrangement is so proportioned that increments of current in U will vary the shunt at V, or the resistance at V in shunt to H, in such way that H shall receive only the square roots of the current in the circuit. The variations are, however, not so smooth and delicate as they are with alternating currents in the arrangement above described.

A variable resistance, or resistance whose amount can be set or varied, may be added as a shunt around the coil U, as in Fig. 1, to standardise the readings of the meter. So arranged, the apparatus will register in proportion to the number of lights used and the time of use.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

'THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

MAJOR MARINDIN'S REPORT.

Although Major MARINDIN has lost very little time in submitting to the Board of Trade his report upon the prolonged Inquiry into the London Provisional Orders, yet we think it will be very generally admitted that the report bears every mark of careful and intelligent consideration, and that in its general lines the policy therein laid down is probably as satisfactory and as practicable as any which could have been devised. Before referring to the other features of the report, which are common to the Orders as a whole, we may say a few words upon the allocation of areas adopted. As we ventured to surmise at the close of the Inquiry, Major MARINDIN has preferred to deal with the cases before him upon their individual merits, and he has not pronounced any sweeping verdict for or against the admission of more than one company into the same area. In the result, whilst there are several cases such as Kensington, where the parish is divided amongst two or more companies, there are but five instances (those of St. George's, Hanover-square; Chelsea (part of); St. James's, Westminster; a small portion of Lambeth, and a small portion of St. Martin-in-the-Fields) where two companies are granted concurrent powers over the same area. In these cases

Digitized by Google

the general principle by which the Inspector has been guided is that one at least of the competing companies should provide a direct-current system, in order to obtain the convenience of working motors. Looking broadly at the results of its application, we have nothing to say against this principle; but it should be remembered that its significance is almost certainly merely of a temporary character. We shall, however, have an opportunity of witnessing the practical working both of direct competition and of the districting system under varying conditions and upon widely different scales.

It will be seen that, with the exception of the Electrical Power Storage Company, whose applications for Paddington and St. Martin's are both refused, and the Chelsea Company, who have lost their Belgravia Order, all the minor companies have been allotted the areas for which they have applied, although in certain cases they will have to compete either with the London or with the Metropolitan Companies. With regard to the division of territory between the two larger Companies, it appears to us that the London Company has received the lion's share, at least as regards extent of territory, while it has also obtained a footing into the coveted district immediately west of Charing-cross. The Metropolitan Company has obtained practically the whole of the West Central area for which it applied, but has lost the valuable districts of St. Margaret and St. John, Westminster, and St. George's, Hanover-square, in which quarters the London Company will be in direct competition with local direct-current stations. Further West, the Metropolitan has lost Paddington—which remains in the hands of the Vestry—but has retained the important district of Marylebone. In the South, it has lost St. Saviour's, but retains Lambeth, Clapham, and Streatham. The London Company loses Marylebone, Clerkenwell (provisionally), the Strand, St. Giles, and Holborn (all of which go to the Metropolitan), and St. Pancras (which remains unappropriated). It retains St. Martin's, the largest part of Westminster, St. George's, Hanover-square, Chelsea, Greenwich, Rotherhithe, Bermondsey, Lambeth (part of), and the Borough. The London Company will find themselves in competition with others in every part of their area except in the South-Eastern districts, from which we venture to surmise that the Inspector has been considerably impressed with the argument that the Ferranti system is of an exceptionally "experimental" character.

With regard to the City, Major MARINDIN sees no reason for departing from the principle applied to the rest of the Metropolitan area; and he urges the Commissioners of Sewers, who are acting for the Corporation, to consent to the division of the City area between the London and the Metropolitan Companies. An incidental objection to this proposal will probably arise from the fact that the Commissioners have already obtained tenders for the lighting of the City; and it is understood that the Anglo-American Brush Company, which has a certain claim to be considered in any such scheme, is one of the companies tendering. The Brush Company would thus be entirely shut out from the undertaking if Major MARINDIN's suggestion were adopted.

As regards the Vestries, they ought to be well content so far, for in one or two instances only have their objections been wholly or partially overruled. In the majority of cases, however, the opposition of the Vestry was confined to a few points of detail, and in these matters Major MARINDIN has wisely laid down the general principle that throughout the Metropolitan area the Provisional Orders shall all be drawn to a uniform model. The Board may therefore shortly be expected to issue a Model Order applicable to all companies and districts alike. It is a little unfortunate, however, that provision could not in some way have been made whereby the parties concerned would have had an opportunity of stating any objection to the terms of this Model Order before its final issue. At the recent Inquiry one company or Vestry may have objected to one clause and another to another, whereas a change in both clauses would possibly be objectionable to both parties. The matter is one of considerable importance, but it is difficult to see what remedy can now be provided unless the Board will consent to submit the Model Order for the consideration of the Chamber of Commerce.

Amongst the remaining proposals applicable to the Metropolis as a whole we may note the fixing of the maximum price at 8d. per unit, and the adoption of a sliding scale to come into force when the dividend reaches 10 per cent. It is, moreover, suggested that in the Model Order a clause should be inserted providing that at the end of seven years the question should be subject to revision by the Board. We may note, incidentally, that the Chelsea Company, under their Act of 1886, are entitled to charge 10d. per unit; this consideration probably had some weight with the Inspector when he decided to admit the London Company to their territory.

In a letter addressed to the Chairman of the London County Council, the BOARD of TRADE signifies its intention of adopting the recommendations of the Inspector as regards the allocation of districts, subject to any observations which the Council may wish to offer. The County Council, as is well known, has at present no actual jurisdiction in the matter, but its potential powers of interference are so considerable that expediency as well as courtesy probably dictated this frank recognition of the Council's right to be consulted. The Council will, we trust, have the good sense to perceive, however, that it will not be acting wisely if it interferes needlessly in matters with which the Board of Trade must be far more competent to deal.

RECALESCENCE OF IRON.*

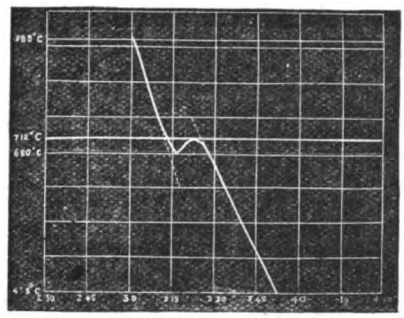
BY DR. J. HOPKINSON, F.R.S.

Prof. Barrett has observed that if an iron wire be heated to a bright redness and then be allowed to cool, that this cooling does not go on continuously, but that after the wire has sunk to a very dull red it suddenly becomes brighter and then continues to cool down. He surmised that the temperature at which this occurs is the temperature at which the iron ceases to be magnetisable. In repeating Prof. Barrett's experiments I found no difficulty in obtaining the phenomenon with hard steel wire, but I failed to observe it in the case of soft iron wire or in the case of manganese steel wire. It appeared to be of interest to determine the actual temperature at which the phenomenon occurred and also the amount of heat which was liberated. Although other explanations of the phenomenon have been offered, there can never, I think, have been much doubt that it was due to the liberation of heat owing to some change in the material, and not due to any change in the conductivity or emissive power. My method of experiment was exceedingly simple. I took a cylinder of hard steel 6·3 centimetres long and 5·1 centimetres diameter, cut a groove in it, and wrapped in the groove a copper wire insulated with asbestos. The cylinder was wrapped in a large number of coverings of asbestos paper to retard its cooling; the whole was then heated to a bright redness in a gas furnace, was taken from the furnace and allowed to cool in the open air, the resistance of the copper wire being from time to time observed. The result is plotted in the accompanying curve, in which the ordinates are the logarithms of the increments of resistance above the resistance at the temperature of the room, and the abscissæ are the times. If the specific heat of the material were constant and the rate of loss of heat were proportional to the excess of temperature, the curve would be a straight line. It will be observed that below a certain point this is very nearly the case, but that there is a remarkable wave in the curve. The temperature was observed to be falling rapidly, then to be suddenly retarded, next to increase, then again to fall. The temperature reached in the first descent was 680°C. The temperature to which the iron subsequently ascends is 712°C. The temperature at which another sample of hard steel ceased to be magnetic, determined in the same way by the resistance of a copper coil, was found to be

* Paper read before the Royal Society, March 14, 1889.

Digitized by Google

690°C. This shows that within the limits of errors of observation the temperature of recalescence is that at which the material ceases to be magnetic. This curve gives the material for determining the quantity of heat liberated. The dotted lines in the curve show the continuation of the first and second parts of the curve; the horizontal distance between these approximately represents the time during which the material was giving out heat without fall of



temperature. After the bend in the curve the temperature is falling at the rate of 0·21°C. per second. The distance between the two curves is 810 seconds. It follows that the heat liberated in recalescence of this sample is 173 times the heat liberated when the iron falls in temperature 1°C. With the same sample I have also observed an ascending curve of temperature. There is in this case no reduction of temperature at the point of recalescence, but there is a very substantial reduction in the rate at which the temperature rises.

ALTERNATE-CURRENT WORKING.*

BY W. M. MORDEY.

I wish to state at the commencement that this Paper is not intended as a contribution to the comparison of the relative merits of alternate-current working and of any system of direct-current supply. The discussion of this question has already taken place, and those who took the A.C. side have no reason to be dissatisfied with the result. It may, however, be pointed out that exclusive advocacy of any one particular method of working as being the best for all purposes is not a position that is likely to be taken by any electrical engineer who has any extensive acquaintance with the various requirements and conditions that are met with in practice.

Working Alternators Parallel, and Best Principles of Construction for Alternators.

This is a matter of very great scientific interest, and of still greater practical importance. It is not too much to say that the complete success of the transformer system of supply depends to a great extent upon whether alternators can be quite easily and successfully worked parallel. This has been strongly insisted upon, especially by the opponents of that system. The importance attached to it arises partly from the fact that the most economical method of supply is that of using always the smallest plant that will do the work, and increasing or decreasing the number of generating units in operation according to the fluctuations of the demand. To do this most conveniently, the alternators should be worked parallel, and ought to be capable of being put in and out of circuit easily, and without causing even a momentary flicker or interruption of the light. The use of a large machine and engine for the small day supply is especially to be avoided. In almost all cases it is desirable to have a comparatively small set of plant for this work, even where large machines are used for the heavy evening work.

Another argument in favour of parallel working, as against the use of very large machines, is that it reduces the cost of the spare plant. Thus, if a station is provided with one or two machines and engines for the full load, the spare plant is equal in cost to the working plant, or perhaps to one-half as much. If, however, smaller generating units are employed, one set in four may be considered a safe allowance.

The history of parallel working of alternators may be briefly sketched.

In 1868 Wilde described parallel working and synchronous action of generators, and so nearly obtained synchronous motor action that it is extraordinary he should have missed it.†

In 1882-3 Dr. Hopkinson,* not knowing of Wilde's work, arrived theoretically at the conclusion that it was possible to work alternators parallel, but not in series, and subsequently demonstrated the fact by trials made, in conjunction with Prof. Adams, on the De Meritens machines at the South Foreland Lighthouse, which were run parallel and as motors. This was all laid before this Society at the time, and was very fully discussed.†

In the course of this discussion in 1884, Mr. Alexander Siemens described some experiments showing that the Siemens alternate-current machine ran as a motor.‡ This is interesting as being, so far as I know, the only recorded instance of an alternator without iron in the armature being run as a motor. It will be remembered that the Wilde and De Meritens machines had iron cores. These experiments of Mr. Siemens were not very successful, the motor frequently stopping suddenly even when doing very little work; but they were of value for comparative purposes.

Passing over the next few years, we find that the use of alternators had become of great importance on account of the growth and development of the transformer method of distribution, and that there was and is a certain amount of doubt and hesitation about working parallel. It is recognised that it has been and can be accomplished, but that the arrangement is not one to be thoroughly and completely depended upon in every case. And there is sufficient justification for this doubtfulness. The present opinion may be fairly stated as follows:—Alternators may be successfully run in parallel if they have a good deal of self-induction, and to secure this it is better that they should have iron-cored armatures.

In his recent Paper on "Alternate-Current Machinery," before the Institute of Civil Engineers,§ Mr. Kapp dealt at considerable length with this part of the subject, and his views, I need not say, may be accepted as quite correctly representing the current state of knowledge and opinion. Referring to alternators that have self-induction negligible, Mr. Kapp says:—"Machines of this type can only be run in parallel if the strength of their field is adjusted with almost mathematical precision, and as this would require more skill and attention than is available with the ordinary staff of a central station, such machines are practically unfit for parallel working. To make them fit for this method of working, either the armature resistance or the self-induction must be increased. An increase of resistance, in order to be effective, would have to be so considerable as to seriously prejudice the electrical efficiency of the machine, and this expedient may therefore be dismissed as impracticable. The other plan of increasing the self-induction is not open to the same objection. It has the effect of lowering the plant efficiency, but its influence upon the electrical efficiency is only indirect, and so small that it may be neglected. From the foregoing, it will be readily seen that the only and sufficient condition for successful parallel working is a sensible amount of self-induction in the armature circuit. If the armature itself does not possess the quality in a sufficient degree, a choking coil of suitable self-induction must be inserted into the circuit of each machine. The results here arrived at, by a mere theoretical investigation, are entirely borne out in practice. It is well known that alternators having no iron in their armatures cannot be run in parallel, except by the adoption of some such expedient as choking coils; also that parallel running is feasible with those alternators which have iron-cored armatures, and then with different degrees of security."

Now this is a very serious state of affairs, for it really means, if true, that the only machines suitable for central station supply are those that, on account of their high self-induction and resistance, are bad regulators that will not bear any considerable change of load without varying a good deal in E.M.F., and that are wasteful on open circuit.

For my part, I have seen enough of the use of iron in armatures to wish to do without it if I can, and I have repeatedly pointed out that, if iron is really necessary, the armature is the very worst place to put it. For the purpose of increasing the self-induction it can be much better used outside of the machine, and put in some place where it is not subject to all the losses, restrictions, and disadvantages that necessarily accompany its employment in the core of an armature. If it is not in the armature it can be entirely removed when not required for the purpose for which it is thought to be necessary—that is, when only one machine is in use. To put iron in an armature merely to increase self-induction appears to show a want of common ingenuity and an absence of the sense of proportion.

But let us examine the evidence on this matter, in order to see what basis of fact there is for the present views.

In the first place, it will be found that the use of iron armatures is not in all cases to be relied on to give successful parallel working. In the discussion last year, Mr. Gordon, who has had very considerable experience, and who used iron largely in his machine,

* Paper read before the Institution of Electrical Engineers yesterday (Thursday) evening.

warned us in strong terms against working in parallel. He said :* "We know that experiments have been made by coupling a number of small alternate-current machines together, and at the South Foreland they were successful, but that was because they were working on arc lamps"—a little elucidation, perhaps, is necessary here. "Many of us have tried them, and they will, on trial, work together, no doubt, but they do not work together till they have run for three or four minutes; they will in that time jump, and that jumping will take months of life out of the 40,000 lamps. That alone is rather a serious difficulty in coupling machines together, and I think we may take it in practice—I am not speaking about the laboratory or experiments—we do not couple machines."

The Zipernowski alternator will, however, work parallel, but apparently not very well; to get it to do so the periodicity has had to be reduced to 42, as we now know.

Further, I have recently seen a communication from the highly experienced makers of a well-known alternator in which iron is used, stating that, if it is desired to run parallel, the machines, engines, and arrangements must be in every way identical; the impression conveyed being that with this machine the greatest care is necessary to ensure a successful result.

Then, again, the large experience of the Westinghouse Company in the United States has shown that their iron-cored alternators will work in parallel under some conditions. We are told that, with these machines, "parallel coupling always succeeds when they are loaded to about half their maximum output or over, but that machines working under a less load cannot with certainty be so coupled."

But the other day Prof. Forbes described† successful parallel working with the iron-cored Lowrie-Parker alternators at West Brompton, even with very light loads.

Thus it will be seen that we have evidence ranging from complete failure to complete success with iron-cored machines.

It is proved, then, that the presence of iron is not alone sufficient to ensure success, for the use of iron is associated equally with failure and with success.

That the success attained is complete only as regards the fact of synchronism is shown by the following extract from Prof. Forbes' remarks in the discussion on Mr. Kapp's Paper, which I quote at some length, because Prof. Forbes has taken every opportunity of ascertaining, by personal observation, what is being done, and because he gives us what is alone of much service at the present stage, viz., the independent record of actual facts, and tells us clearly what the real difficulties are.

The passage is‡ :—"The question of parallel working was one which had been very much discussed as to whether it was desirable or possible. . . . It was always possible, as Mr. Kapp said, with machines which had a very high self-induction—machines in which the armature had a great mass of iron in it. At the same time, the introduction of that self-induction into a machine reduced what Mr. Kapp called the plant-efficiency of the dynamo machine; and if they could work out, as he believed engineers would work out, some better means of making machines work in parallel, it would be very desirable. Another reason why the heavy self-induction was injurious was that it required such continued attention on the part of those in the station to see that the pressure was maintained constant. The electrical pressure varied so much that the quantity of current being developed, as shown by the table of curves, was seriously affected, and constant attention was required to keep such a machine regulated to the right pressure; whereas a machine which had no self-induction, or very little, gave off the same electric pressure, or nearly so, whatever the current might be, so long as the speed was maintained constant. As to the possibility of working conveniently in parallel with those machines, he might say that the experience of America had been completely against it. It was there found that it was possible to work in parallel, but that it enormously increased the amount of skilled attention required in a central station."

This is a very strong condemnation of the present system of obtaining synchronism, and at the end of his "Central Stations" Paper § Prof. Forbes returns to the subject in these words :—"I venture to think, however, that the plan now universally proposed for making machines work in parallel will not long be tolerated. This is to introduce into the machine a large amount of injurious self-induction, thus diminishing the plant efficiency, and rendering the equalising of pressure with various loads very difficult."

Turning now from alternators with to those without iron-cored armatures, we are brought face to face with the serious fact that, in spite of the many inconveniences connected with the use of very large machines, Mr. Ferranti is laying down the Deptford station to work with engines and alternators, each of several thousands of horse-power, and is depending upon the employment of spare engines and machines of corresponding size to prevent or to minimise the risk of wholesale extinction of the lights. It is understood that one of the principal reasons for doing this is that parallel working is not to be relied on.

The next question is, Is it clear that, in order to be able to run them parallel, or as synchronising motors (for I need not say that the two qualities are inseparable and are, in fact, identical), alternators should be bad regulators, should have large self-induction, or high resistance, or both? I think not. I have mentioned Mr. Gordon's machines, which certainly had the first of those qualities, but they would not run parallel. Other machines that I have referred to, and whose parallel working is not to be depended upon, are at any rate not remarkable for absence of self-induction.

Again, Is the absence of iron from the armature cores alone sufficient to deprive a machine of self-induction, and to give it a straight characteristic? I think not; for I have tested machines that had no iron, but that had a good deal of resistance, very considerable self-induction, that had very crooked characteristics, and yet that would not run parallel under any circumstances whatever.

So we see that neither a bent characteristic, nor self-induction, nor resistance, nor the use of iron cores, nor even the simultaneous possession of the whole of these admirable features and qualities—that none of these things is the secret of successful parallel working.

Perhaps—and this is a dreadful reflection—it is the exact opposite of all these!

Now I am in the unenviable position of being out of accord with the theories, the practice, the principles and the explanations of the very able men who have lately written, spoken, and worked on this subject. I have no doubt that all they have said is perfectly correct, so far as their difficulties are concerned—that they have experienced considerable trouble in working parallel, and have even in some cases met with actual failure. But this was partly because they have been unfortunate or unwise in the apparatus they have used, and partly because the principles that have been relied on to ensure success have not been in all respects suited to the case.

Although the conditions of the two problems are not in all points similar, I very respectfully submit that we are in danger of repeating the old mistake that was made regarding direct-current motors. We were taught that self-induction in the armatures was good, and that a special form and special proportions should be given to such motors; and I was very unorthodox when, in 1886,* I asserted that self-induction was not a virtue to be cultivated in motors any more than in dynamos, and generally that a good motor was a good dynamo, and *vice versâ*. However, it is some satisfaction to know that the views I then expressed have received the sanction of general practice, although I am afraid that in the eyes of Profs. Ayton and Perry those views remain as unorthodox as ever.

Now, I am prepared to take a precisely similar stand with regard to alternators, and to submit for your criticism the view that a perfect alternator for any and every purpose should have no resistance and no self-induction.

I prefer to regard the question of alternate-current parallel working as a question very largely depending upon what are the best principles of construction for synchronising alternate-current motors. It is very much better and simpler to look at it from this point of view than from any other, and I venture to assert, in spite of all that has been said to the contrary, that if alternators are made, amongst other things, with the least possible self-induction and the lowest practicable resistance, they will not only be the best alternators, but they will best run parallel, and will do so because they will then be the best synchronising motors.

I think that even the advocates of large self-induction will admit that that quality does not improve an alternator *per se*—they only introduce and tolerate it on account of its supposed bearing on parallel working (I could quote a number of such admissions); but it appears to me that, properly regarded, self-induction is not even a necessary evil—it is an unmitigated evil. It is an evil even for this narrow and restricted purpose.

What does it do? When machines are getting out of phase, it steps in and prevents that ready transfer of current which is required in order to check the leading machine and to accelerate the lagging machine. It prevents the latter from immediately and unhesitatingly developing those motor properties which lie at the root of successful synchronism. The foundation of parallel working should be that the prime motors are under the control of the generators. The question turns, therefore, partly on the qualities of the prime motor, but much more largely on the motor qualities of the alternators.

I am prepared to admit that if the tendency of the prime motor to lead or to lag is so great that under no circumstances can it be controlled—and this may arise either from excessive power on the part of a prime motor or from defect of motor power in an alternator—then large self-induction or resistance may be of use in order

to prevent one or more of the machines being burnt up, not, however, as useful and not as effective as a safety fuse; but self-induction under such circumstances is not an assistance to parallel working—quite the contrary. If it were absent, probably the machines would run parallel all right. They would be much less likely to be burnt up without self-induction than with it. Self-induction is useful because it prevents the machine which ought not to have it from being burnt up because it has it.

Now I will briefly describe some experiments with two of my alternators, each made for 2,000 volts, and each capable of working continuously at 35,000 to 40,000 watts, or, say, 50 E.H.P. output.

Arrangement.—Each machine was driven by a 75 indicated horse-power Fowler engine. These engines were similar, their normal speed of working being 120 revolutions per minute. Each of the engines, which were not coupled or connected in any way, was provided with a heavy fly-wheel, and drove, besides an alternator, a heavy and wasteful double (and in one case treble) set of counter-shafts provided with a large number of belts, fitted to an arrangement of fast-and-loose pulleys for convenience of testing all sorts and conditions of dynamos. I mention this as showing that the momentum in each case was very considerable.

In order to make the test as onerous as possible, the pulleys used were such that one engine had to run at 130 revolutions, while the other ran at 90 revolutions, when the alternators were at their normal speed of 650 revolutions per minute.

(1.) The alternators were run up to full speed, and each excited to give 2,000 volts. When in phase they were switched parallel without any external load, and without any impedance coils or resistance between them.

They ran parallel perfectly.

(2.) A considerable inductionless load was then put on, varied, and taken off. They ran equally well under all circumstances.

(3.) They were uncoupled, and then, the load being connected to the mains, they were suddenly and simultaneously switched parallel and on to the mains with perfect success.

(4.) One alternator was excited to give 1,000 volts, the other giving 2,000 volts. They were then switched parallel, and went into step perfectly, giving a terminal P.D. of about 1,500 volts. No impedance or resistance was used in this or in any other case. A load was then put on without affecting their behaviour.

(5.) With one machine at 1,000 volts and the other at 2,000 volts they were switched parallel *when out of phase*, and instantly went into step. A large current appeared to pass between them for a fraction of a second, but not nearly long enough to enable it to be measured or to do any harm.

(6.) They were then left running parallel while one was disconnected from the engine by its belt being shifted from the fast to the loose pulley. It continued to run as a motor synchronously. A load of lamps was at the same time on the circuit.

(7.) The two machines were then uncoupled and excited up to 2,000 volts. They were then switched parallel when out of phase and without any external load, and went into step instantly.

(8.) Whilst running as in (7), steam was suddenly and entirely shut off one engine. The alternators kept in step perfectly, one acting as a motor, and driving the large engine and all the heavy counter-shafting and belts. It was impossible to tell, except by the top of the belt becoming tight instead of the bottom, which machine was the motor.

To find the power exerted by the alternator acting as a motor (in 8), a direct-current motor was put in its place, and the power required to drive the engine and shafting was found to be 20 horse-power.

It may be pointed out that these tests were made under the most exacting and onerous conditions that could possibly be imposed, and particularly I would point out that on account of the very great momentum of the revolving masses nothing but the strongest and most instantaneous motor action could have kept the machines in phase. There never was a single case when they got out of step, even momentarily, or when subjected to sudden and violent variations of load. When it is considered that, in order to secure this result, it was imperative that the control of all that mass should be exerted in a fraction of $\frac{1}{200}$ of a second (the periodicity being 100), it will be recognised that there was no time to be lost, and that the use of any self-induction or resistance, or of anything else that could in any way choke, retard, check, or interfere with the strength and instantaneity of the action, was above all things to be avoided.

I should mention that the machines apparently synchronised equally well at speeds varying very considerably.

As to the self-induction of the machine itself, that is quite negligible. Its characteristic (Fig. 1) is nearly straight, about half the drop in the curve being due to resistance and half to self-induction.

Here was a machine generally allowed to be good when working singly, but possessing all the qualities that have been stated as unfitting it for parallel work, tested under all the conditions that are recognised as most trying, even for those types of alternators which are universally, and I believe erroneously, regarded as best suited for parallel work, and behaving throughout in a manner that simply left nothing to be desired, and carrying unimpaired into parallel work those features which it possesses when run singly.

I trust that I have now said enough to justify the views I have expressed.

A few particulars of this machine may be of interest. It now takes 500 watts to excite it at full load, and rather less than 400 watts on open circuit with full E.M.F. The efficiency when working with a light load is very high. The power required to run at full speed with full E.M.F. but no external load is 3 horse-power, of which 1·5 horse-power is ordinary mechanical loss in the bearings, &c., and 1·5 horse-power is electrical waste in the armature conductors and supports. This is from a most careful test, and shows that, so far as economy is concerned, with light loads the machine does not leave much to be desired. This is really of very great importance, for the expense connected with central station working during the long hours of daylight may be a serious item.

Alternate-Current Motors.

The bearing of the foregoing on the great and vital question of the construction of alternate-current motors is obvious. Much work has been done of late on this subject, and no doubt considerable success has been met with, but the use of alternators as simple synchronising motors has not appeared to attract much attention, probably because it is not known what excellent results may be obtained in this direction, and partly because of their inability to start from rest.

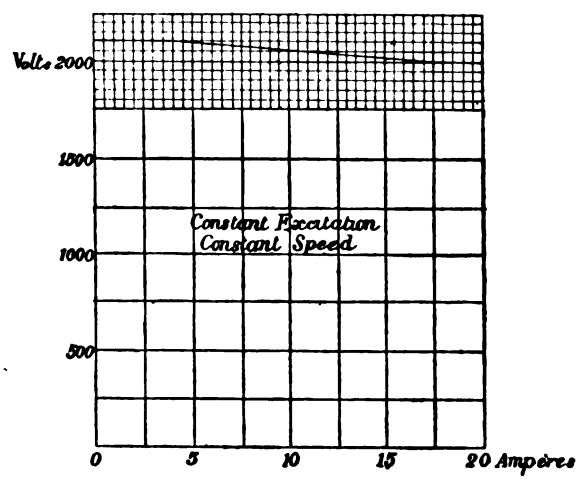

Fig. 1.—Characteristic.

The experiments just described, and others that I have carried out, showed what perfect self-governors such motors are. Not only do they maintain synchronism, but they possess an inherent economy which is most valuable. Just enough current passes through them to keep them in step and to do the work imposed on them. They become generators, and do work on the circuit, if from any cause there is a tendency for them to run faster than the generator.

I have devised a very simple means of starting such motors, which at a small expense removes the only drawback to their employment. The exciter, which is geared directly in some way with the alternator, is used, in conjunction with a small accumulator, as a direct-current motor to start the alternator. When synchronism is attained the latter is simply switched into circuit. It will be obvious that a small battery capable of a heavy discharge for a minute or two is all that is required. This is recharged by the exciter. I need not go into the details of the arrangements. This is perfectly practical. I should have no hesitation in running these alternators in regular work as motors, and should expect to find their "commercial efficiency" very nearly or quite 90 per cent.—about the same efficiency, whatever it is, that they possess as generators. For instance, the machines alluded to will work as motors at a useful output of 50 horse-power with this efficiency.

And here is another advantage in getting alternators economical when on open circuit. By doing so it becomes possible to use the very small exciter as a direct-current motor to get them up to the synchronising speed.

In many situations a synchronising A.C. motor will fulfil all requirements, and will do so with fewer drawbacks than any other kind of electric motor whatever. It will be a better regulator, more economical, less troublesome to look after, much safer to handle, and (what is of very great importance in connection with

Digitized by Google

the transmission of large powers to a distance) the difficulty of dealing with high pressures, which is so serious with direct-current motors, is very easily overcome, for not only will alternators stand a higher tension in themselves, but, if necessary, transformers may be used to reduce the pressure between mains and motor.

(To be continued.)

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"On Lightning, Lightning Conductors, and Lightning Protectors."*

BY DR. OLIVER LODGE, F.R.S.

INSTRUCTIVE EXTRACTS FROM REPORTS OF DAMAGE BY LIGHTNING.

(Concluded from page 42, Vol. XXII.)

46. I may call attention to some apparently sound doctrines in a paper by Captain Bucknill, R.E., abstracted in *L.R.C.*, p. 242.

That lightning can penetrate into collieries is proved by an account of a meeting of Mining Engineers (*L.R.C.*, p. 237).

The same sort of thing is illustrated by the accident at Bootham Bar, York (*L.R.C.*, p. 219), when the lightning struck down into a cavity surrounded by high buildings with lead roofs, iron rain-water pipe, and an iron portcullis, to get at a street bracket 11ft. 6in. above the pavement, melting its pipe, and setting a house on fire by the large flame produced (*L.R.C.*, p. 219).

47. That the existence of gas-pipes make houses more difficult to protect, and in fact causes dwelling-houses to require almost as much attention as powder magazines, can be illustrated by a good number of extracts. The following may serve (*L.R.C.*, p. 239):—

"On July 13, 1880, during a thunderstorm, the large 400-light gas-meter of this mill, though locked up in a cellar, and with no light near it, exploded, and the gas, which is supplied through a four-inch main, was ignited. This was repaired, but on July 5, 1881, during another thunderstorm, precisely the same accident occurred."

From an interesting report, signed "J. Gavey," on damage to a church at Cardiff (*L.R.C.*, p. 218), I make the following extract:—

"On examining more closely the surroundings of the lightning conductor, I observed that the church gas-pipe, an iron one, about 1¼ in. in diameter, passed through the wall of the building about 6ft. from the conductor, and was carried in a direction corresponding with the hole caused by the explosion (see plan). I immediately concluded that this explosion was due to the current breaking across from the conductor to the gas-pipe, and on opening up the hole I found this to be the fact. The conductor crossed the gas-pipe at nearly a right angle, being about a foot above it. The under portion of the conductor bore evident marks of fusion, and, more interesting still, the gas-pipe was slightly coated with a very thin deposit of copper, so thin that it perished in my attempt to remove it; but still there was an undoubted coating at one spot."

Continuing the account of this kind of damage, the following interesting remarks by Prof. Kirchhoff have a bearing on the important practical question whether gas-pipes should or should not be utilised for earth; but their main utility lies in the proof afforded of the unique kind of danger which gas-pipes introduce:—

INJURY TO GAS AND WATER PIPES BY LIGHTNING.†

of Electrical Engineers, No. 77, Vol. XVIII., 1889, of Papers by Prof. W. Kohlrausch and Voller respectively.

The city gas company of Berlin having expressed the fear that gas-pipes may be injured by lightning passing down a rod that is connected with the pipes, Prof. Kirchhoff has published the following reply:—

"As the erection of lightning rods is older than the system of gas and water pipes as they now exist in nearly all large cities, we find scarcely anything in early literature in regard to connecting the earth end of lightning rods with these metallic pipes, and in modern times most manufacturers of lightning rods, when putting them up, pay no attention to pipes in or near the building that is to be protected." Kirchhoff is of the opinion, supported by the views of a series of professional authorities, that the frequent recent cases of injury from lightning to buildings that had been protected for years by their rods, are due to a neglect of these large masses of metal. The Nicolai Church, in Griefswald, has been frequently struck by lightning, but was protected from injury by its rods. In 1876, however, lightning struck the tower and set it on fire. A few weeks before the church had had gas-pipes put in it. No one seems to have thought that the new masses of metal which had been brought into the church could have any effect on the course of the lightning, otherwise the lightning-rods would have been connected with the gas-pipes, or the earth connection been prolonged to proximity with the pipe. A similar circumstance occurred in the Nicolai Church in Stralsund. The lightning destroyed the rod in many places, although it received several strokes in 1856, and conducted them safely to the earth. Here, too, the cause of injury was in the neglect of the gas-pipes, which were first laid in the neighbourhood of the church in 1856, shortly before the lightning struck it. The injury done to the school-house in Elmshorn, in 1876, and to the St. Lawrence Church, at Itzehoe, in 1877, both buildings being provided with rods, could have been avoided if the rods had been connected with the adjacent gas-pipes.

"If it were possible," says Kirchhoff, "to make the earth connection so large that the resistance which the electric current meets with when it leaves the metallic conducting surface of the rod to enter the moist earth, or earth water, would be zero, then it would be unnecessary to connect the rods with the gas and water pipes. We are not able, even at immense expense, to make the earth connections so large as to compete with the conducting power of metallic gas and water pipes, the total length of which is frequently many miles, and the surface in contact with the moist earth is thousands of square miles. Hence the electric current prefers for its discharge the extensive net of the system of pipes to that of the earth connection of the rods, and this alone is the cause of the lightning leaving its own conductor."

[This, like many another theoretical remark, is not to be supposed true.—O. J. L.]

Regarding the fear that gas and water pipes could be injured, he further says: "I know of no case where lightning has destroyed a gas or water pipe which was connected with the lightning-rod, but I do know cases already in which the pipes were destroyed by lightning because they were not connected with it. In May, 1809, lightning struck the rod on Count von Seefeld's castle, and sprang from it to a small water-pipe, which was about 80 metres from the end of the rod, and burst it. Another case happened in Basel, July 9, 1849. In a violent shower one stroke of lightning followed the rod on a house down into the earth, then jumped from it to a city water-pipe, a metre distant, made of cast iron. It destroyed several lengths of pipe which were packed at the joints with pitch and hemp. A third case, which was related to me by Prof. Helmholtz, occurred last year in Gratz. Then, too, the lightning left the rod and sprang over to the city gas-pipes; even a gas explosion is said to have resulted. In all three cases the rods were not connected with the pipes. If they had been connected the mechanical effect of lighting on the metallic pipes would have been null in the first and third cases, and in the second the damage would have been slight. If the water-pipes in Basel had been joined with lead instead of pitch no mechanical effect could have been produced. The mechanical effect of an electrical discharge is greatest where the electric fluid springs from one body to another. The wider this jump the more powerful is the mechanical effect. The electrical discharge of a thunder-cloud upon the point of a lightning-rod may melt or bend it, while the rod itself remains uninjured. If the conductor, however, is insufficient to receive and carry off the charge of electricity, it will leap from the conductor to another body. Where the lightning leaves the conductor, its mechanical effect is again exerted, so that the rod is torn, melted, or bent. So, too, is that spot of the body on which it leaps. In the examples above given it was a lead pipe in the first place, a gas-pipe in the last place, to which the lightning leaped when it left the rod, and which were destroyed. Such injuries to water and gas pipes near lightning rods must certainly be quite frequent. It would be desirable to bring them to light, so as to obtain proof that it is more advantageous, both for the rods and the building which it protects, as well as for the gas and water pipes, to have both intimately connected. Finally, I would mention two cases of lightning striking rods closely united with the gas and water pipes. The first happened in Düsseldorf, July 23, 1878, on the new Art Academy; the other August 19 last year, at Steglitz. In both cases the lightning rod, the buildings, and the pipes were uninjured."*

48. That lightning sometimes does things which is on the hitherto available views inexplicable is evidenced by the following record by one, who, of all others, made lightning conductors his hobby, who acquired an immense amount of experience concerning them, and to whom the carrying out of probably the most perfect system of protection in actual use is largely due. I mean the late M. Melsens:—

* Paper read before the Institution of Electrical Engineers on Thursday, April 25, 1889.

*Note on the Lightning Flash at Antwerp Railway Station, July 10th, 1865. By M. Melsens.**

"I have described this lightning stroke, which was very harmless, since all the damage was confined to the breaking of a square of glass in the roof of the covered station of the railway at Antwerp; but in connection with it I found myself confronted by so extraordinary a phenomenon that I had to search through all the descriptions of lightning strokes which might offer a certain analogy to this with which I have to do. It was only on looking through my notes again, and returning several times to the place, that I have ventured to describe this very extraordinary stroke, and I have only published it after a long time, when it seemed to me that I could establish it upon careful observations and experiments which seemed of a nature to corroborate my conclusions. [Mention made of 19 lightning flashes, which present some analogy to that which struck Antwerp Station.]

"A few words are sufficient to show the peculiarity of the phenomenon. The lightning crossed a square of glass and produced in it a hole similar to that which would be produced by a projectile thrown upwards from below at a slow rate, say, from 30 to 50 metres per second, and travelling from earth towards the sky; the edges of the hole were melted. I have given a description of the experiments I made, together with Ruhmkorff, to prove that in reality lightning does travel from the earth towards the sky; the proof which I give of it seems to me decisive.

"The extraordinary fact, as I have remarked, is to see the lightning pass, by means of a very bad conductor, through a square of glass 4 millimetres in thickness, forming a parallelogram of $0^{m}.35 \times 0^{m}.38$, having angles of 83° and 97°.

"The opening produced was at a distance of some centimetres from iron and lead conductors, which were in perfect metallic communication with all the iron of the station. The weight of this latter exceeds 120 tons. But the anomaly does not stop there; to the right and left of the glass roof in which the broken pane was, the covered platform of the station has a roof of zinc No. 13, presenting to the lightning a surface of 3,000 square yards; the weight of this zinc is not less than 15 tons; the three tall rods of the lightning conductor are in immediate metallic contact with this zinc and with the conductor, and the whole is connected to 28 hollow columns, serving to carry off rain-water. The collection of these metals would allow one to suppose that they were well adapted to carry off lightning or any such disturbance easily; but in this instance it despised them, and choose a path entirely unexpected. Let me add that there was a shed some 62 metres from the station built on hollow columns and iron framework, and the greater part of it roofed with zinc; moreover, about 40 metres on the opposite side were more sheds roofed with zinc; the metallic surface was not less than 2,000 square metres. Moreover, in my investigation, I might mention plenty of other metals in communication more or less perfect with the earth, grids, sconces, gas-pipes, telegraph wires, rails, &c. Besides, the whole of the platform may be considered as one large lightning conductor in perfect communication with a very damp earth, and offering hardly any resistance to the passage of the current from the building."

49. Of all the buildings in the world not wholly made of metal, the Hôtel de Ville at Brussels was and is the most perfectly and elaborately protected. No electrician exists but would a year ago have asserted, had he gone over it, that it was absurdly and exaggeratedly safe from damage by lightning. Last July it was struck and set on fire.

The case has been investigated and published in the *Bulletin de la Société Belge d'Electriciens* for September and October, 1888.

It seems to have been owing to secondary or induced electric surgings in a horizontal bar of metal totally disconnected from anything; not pretending to lead toward earth, and being some little distance below a stretch of lightning conductor not offering itself as an object to be struck. On all the old views it was utterly insignificant. However, as a matter of fact, although not struck, although it did not (probably) even receive a side flash, yet the induced surgings set up in it, induced by Maxwell and Heaviside's electro-magnetic waves, were so violent as to ignite some gas and cause a small fire. Had it been connected to the conductor, the sparking from it would probably have been still stronger.

This occurrence, and certain sparkings in the wall paper of the Royal Institution (see *The Electrician* or *Nature*, March, 1889), are plain and straightforward intimations that the old views on the subject of electric conduction are hopelessly and absurdly and dangerously inadequate. It is time that the prophets of that old superstition were slaughtered by the brook Kishon.

Practical Questions.

50. There remains to consider what is to be the practical outcome of all this—what improvements in the erection and testing of lightning conductors are possible. This is a matter well worthy of discussion, and eminently suited to it. It is a matter on which I have not the slightest wish to be dogmatic; and if I make a few apparently definite assertions it is only by way of expressing such judgment as I have able to form at present, and they are to be taken as intended more by way of suggestion and question than anything else.

With this proviso I should be disposed to make some such statements as the following:—

51. All parts of a lightning conductor, from points to roots, should be of one and the same metal, to avoid voltaic action.

52. Joints should be avoided when possible, and should be made substantially when necessary. Allowance for expansion and contraction must not be forgotten.

53. Sharp bends, and corners, and curves, and roundabout paths to earth should be avoided as far as possible.

54. The use of copper for lightning conductors is a needless extravagance.

55. Iron has advantages over every other metal.

56. The shape of cross-section is but little matter. Flat ribbon has a slight advantage over round rod, but not enough to override questions of convenience.

57. Liability to be deflagrated by a powerful flash determines the minimum allowance for size of cross-section. No consideration of conductivity and greater ease of path has the least weight in this connection.

58. It is hopeless to pretend to be able to make the lightning conductor so much the easiest path that all others are protected. All possible paths will share the discharge between them, and a lot of apparently impossible ones.

59. A good and deep earth should in general be provided, independent of water and gas mains.

60. If the conductor at any part of its course goes near water or gas mains it is best to connect it to them.

61. If the place to be protected has water or gas pipes inside it, the conductor should be connected to their mains underground.

62. At all places where water and gas pipes come near each other, and, in general, wherever one metal ramification approaches another, it is best to connect them metallically.

63. The neighbourhood of small-bore fusible gas-pipes and indoor gas-pipes in general should be avoided in erecting a lightning conductor.

64. Into powder magazines and such like places no gas or water pipes should be permitted to enter, unless the whole building is made of metal, and they are elaborately connected to it at the point where they enter.

65. It is not wise to erect very tall pointed rods above the roof of a building.

66. A number of points all along the ridge of a roof is better than only a few.

67. Any part of a building is liable to be struck, and, to make quite secure, every prominent part of the outside should have a rod running along it.

68. Insulated as well as earth-connected bodies are liable to spit off sparks.

69. No complete security can be attained unless the whole building be metal-lined, floor and all.

70. In ordinary houses it may be well to try and insulate the lightning conductor from the walls, so as to lessen the chance of side flash to metal stoves and things inside.

71. In chimneys it may be well to use insulators to protect the bricks from concussion.

72. The cheapest way of protecting an ordinary house is to run common galvanised iron telegraph wire up all the corners, along all the ridges and eaves, and over all the chimneys, taking them down to the earth in several places, and at each place burying a load of coke. Rain-water spouts and other outside metal, if all well connected together, may likewise be utilised.

73. Connecting a lead roof or other such expanse with a lightning conductor is not an unmixed good, for it virtually increases the dangerous proximity of the lightning conductor, and may inadvertently bring it near to many objects which else might have escaped.

74. One of the most difficult things is to know what to connect and what to avoid.

75. The orthodox rule, "Connect all pieces of metal to the lightning conductor," requires modification, thus:—Connect all pieces of metal to each other and to the earth, but not to the lightning conductor.

76. It may be always reckoned safe to earth things independently. It is often not safe to connect them to the lightning conductor, *e.g.*, an inside lining of a chimney should be well earthed, but should not be used as lightning conductor not connected with it. The same with rain-water pipes and gutters. The same also, probably, with lead roofs.

77. In connecting pieces of metal to each other, if they happen to form a nearly closed circuit the circuit should be metallically completed.

* "Paratonnerres Notes et Commentaires," par M. Melsens. Brussels, 1882. Extracted from reports of Belgian Delegates to the Paris Exhibition, 1881.

Digitized by Google

78. Over the top of tall chimneys it is well to take a loop or arch of the lightning conductor, made of any stout and durable metal.

79. Lightning conductors should be always outside and easily visible.

80. A conductor detached from the building to be protected is safer than one in close contact with it.

81. For powder magazines and such like an outer cage surrounding the building, with sky points and earth roots, and an inner cage on the building, with independent earth terminals only, is the safest plan.

82. If under these circumstances there be no gas-pipes nor much ramifying metal work inside the building, and no metal at all going near either cage, the interior may be considered perfectly safe.

83. The inner cage may often be conveniently made of continuous sheet iron. The outer cage need not then be at all small-meshed; in fact, it need be little more than a dozen vertical conductors.

84. The resistance of an earth may be tested in the customary way to guard against actual breaches of contact by rust or workmen; but no overweening confidence must be felt, even though the resistance turn out the thousandth of an ohm or less.

85. A Wimshurst machine and couple of Leyden jars afford a convenient mode of testing a conductor for flagrant defects. The testing should be done in the dusk or in moonlight, so that there may be light enough to work by and yet sparks be visible.

86. Telephones are the handiest things to detect electric surgings in conductors inside the house while discharges are being made to the conductor. But vacuum tubes, gas leaks, Abel's fuses, &c., &c., can also be employed.

87. Another mode of testing can be carried out on an insulated rod, with an induction coil and spark gap after the manner of a great Hertz oscillator. This is probably the most searching plan. Sparks will then be probably obtained from all the gas brackets, water taps, and picture rails in the house.

88. Telegraph stations and houses supplied with electricity from overhead wires should have an efficient lightning protector at the place where the wires enter the house.

89. When a number of houses are wired up together for lighting, even by underground wires, it may be well to disconnect them by means of intervening lightning protectors on the principle of fireproof doors.

90. A central lighting station, having a tall chimney connected to its boilers and dynamos, should be, by a lightning protector, disconnected from the leads which carry the current from it, because a small fraction of a stroke getting into the leads might destroy a number of lamps, especially if they were already working at something like their full power.

91. Telephone arrangements, and any long length of close-packed insulated wires (even underground) should be protected by lightning protectors, else the insulation is apt to be sparked through and spoiled.

ABSTRACT OF DISCUSSION (AUTHORISED REPORT).

In opening the discussion Mr. PREECE said he did not wish to appear as antagonist of Dr. Lodge, but as a defender of the Lightning Rod Conference and the "older Electricians," and as an advocate of "Experience" as distinguished from "Theory." Those of the older school were guided by and had a great veneration for facts, whereas the deductions of theory were based on assumptions guided by mathematics, and were not always true.

Referring to case *a* (steady strain), he contended that no difference of opinion existed, and that this was the case taken up by the Conference. With regard to the relative merits of iron and copper for conductors, the Conference considered the question judicially, and recommended copper chiefly because of its greater durability. He himself always advocated iron, and considered a No. 4 galvanised wire amply sufficient for ordinary conductors. As a proof that self-induction was not ignored by the Conference a passage from the report was quoted, which states that the suddenness of lightning discharges affects the conductivity.

Coming to case *b* (impulsive rush), great difference of opinion exists. Though he had no doubt about the reality of the phenomena shown in Dr. Lodge's experiments by the aid of Wimshurst's machine, yet he contended that the deductions drawn from them were not necessarily true, that Leyden jar discharges were not comparable with lightning flashes, and that the tin plates used to represent clouds differed greatly in conductivity from clouds, which, on the authority of Dr. Lodge, are very imperfect conductors. He considered that the conditions of the experiments more nearly imitated a broken conductor, and mentioned that many similar experiments were made fifty years ago by Mr. Andrew Cross.

As regards the oscillatory character of discharges, all agreed that Dr. Lodge had shown that Leyden jar discharges could be made oscillatory by introduing self-induction, but he (Mr. Preece) thought there was no conclusive evidence that lightning flashes were so. On the contrary, telegraphic records of flashes made by Bain's chemical system, Thomson's recorder, and Wheatstone's receiver show no signs of oscillation. A recent case was described in which a Wheatstone receiver was kept running during a thunderstorm in Anglesea on Sunday, the 5th inst., and the resulting tape was exhibited. Further evidence of the unidirectional character of the current was said to be afforded by the signs of electrolysis exhibited by some conductors which had been broken by flashes. He had also examined wires fused by lightning in which the fusion appeared to have started in the interior, whereas according to Dr. Lodge the current is confined to the outer layers. This, the speaker submitted, tended to disprove the theoretical deductions, and he therefore thought that the fact of telegraphic instruments always being fused inside the coils pointed in the same direction.

Referring to lightning protectors in general use, experience proved that instead of such things being of the "most utterly imperfect kind," they were of immense service, for in the Navy no accident had been recorded since 1872, and in the Post Office Telegraphs not a single pole out of half a million had been damaged. In 1872, before the instruments were fitted with protectors, 19 per cent. of the instruments in use were damaged, but now the percentage is reduced to 1·3, and this he believes due to the non-protected instruments still in use.

Several conclusions of the Lightning Rod Conference had been severely criticised by Dr. Lodge in section 39 of his Paper, particularly those relating to the protection afforded by well-earthed conductors; and in reply to this criticism Mr. Preece said he was quite prepared to clasp a good conductor during a storm or even to sit on a barrel of gunpowder through which the conductor passed.

Mr. C. W. VINCENT, speaking of oscillations, said that he assisted Faraday in making experiments on the discharge of a large Leyden battery through various materials, but no signs of oscillation were noticed, although cases of intermittent discharge were frequently detected.

Mr. FARQUHARSON described a singular case of damage to H.M.S. "Coquette," in which part of the conductor passing from the mast to the copper sheathing of the vessel was torn away from the beam to which it had been attached. The only defect found in the conductor was a bad joint near the top, and he could never understand how this defect could cause the observed effect.

Mr. J. WIMSHURST considered that there was nothing very new in the impulsive rush, for he had been acquainted with it for some years. As regards the protection afforded by points against an impulsive rush, this depended greatly on whether the cloud was positively or negatively electrified. To show this a dome and point were placed on the lower of two insulated metal plates, and Leyden jars discharged into the upper. When the top plate was + the point was struck equally with the dome when both were at the same height, but when the electrification was reversed the point afforded a great protection. This difference is of consequence in Dr. Lodge's "bye-pass" experiments, and he (Mr. Wimshurst) had found that putting on the bye-pass reversed the direction of the spark across the air space.

Prof. W. G. ADAMS said that as chairman of the Lightning Rod Conference he thought the work done by that body had been misrepresented and unfairly criticised, for its objects were to examine and report on what was then known on the subject, and to condense existing knowledge so as to form a scientific basis for future practice, and these objects, he considered, were well carried out. He acknowledged that Leyden jar discharges produced remarkable effects then unthought of, but considered the statement that lightning flashes were strictly analogous unproved. As illustrating the truth of the older views the case of Brussels Town Hall was cited. This building, although elaborately protected on M. Melsen's system, has been recently struck, thus proving that the adverse opinion expressed by the Conference on the system adopted to be well founded. Another case in which the views of the Conference received confirmation occurred at the South Foreland Lighthouse in 1885. The flash struck the lantern, leaped to the electric lamp, passed through a long cable to the magneto machines, and thence by way of the engine-room conductor to a well 280ft. deep into which the conductor was earthed. The lighthouse conductor, where seen, was in perfect order, but the earth plate was found buried about 18in. below a gravel path resting on dry chalk. A man standing within a foot of the spark as it passed to the electric lamp felt no shock.

Prof. FITZGERALD, on rising, said he had said nearly all he had to say at Bath, but he wished to point out that the data now brought forward by Mr. Preece did not prove the non-existence of oscillations, for in all discharges—whether oscillatory or not—there is a definite flow in one direction which would produce the telegraphic records. Referring to Dr. Lodge's Paper, he said the weak point was the assumption that clouds behaved like good conductors, for it was well known that in horizontal directions they were very bad conductors. Of course it was possible that a shower might make them good conductors vertically; but this was a point on which no reliable data existed. Before Dr. Lodge's experiments the speaker said it would have been very difficult to account for the setting fire to the Hôtel de Ville at Brussels by sparks from an isolated bar of metal, and although the Lightning Rod Conference had done much good work, there were still many obscure points requiring experimental examination.

At this stage of the discussion Dr. LODGE (who is unable to attend the next meeting) briefly replied to some of the questions raised. With regard to Experience *v.* Theory, he considered that theory, guided by experiment, more likely to make progress than unguided experience. Owing to lack of theory Edison called into existence "etheric force" to explain phenomena of a character similar to those produced by electric surgings, and M. Mascart had observed similar phenomena, but had not described them because he could not understand them. Mr. Preece had said that no difference existed between them as regards case *a*, but this Dr. Lodge thought was not correct, for he maintained that surgings occur in case *a* as well as in case *b*; and he could not admit that when there was no oscillation there was no self-induction, for self-induction existed in every circuit.

Judging from Preece and Sivewright's telegraphy he concluded that lightning protectors frequently failed, and to be really efficient no single failure should occur.

Referring to Mr. Wimshurst's experiment, he said that he had not

Digitized by Google

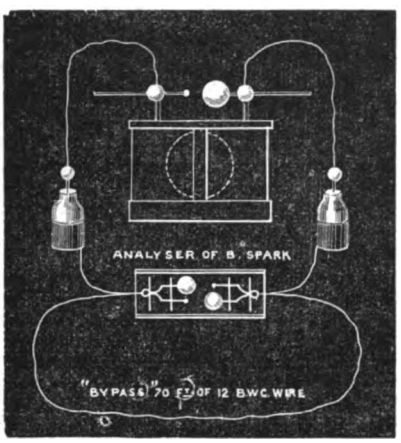
noticed any difference between the different protective effect of points with charges of opposite sign, for he never troubled himself about the matter of sign.

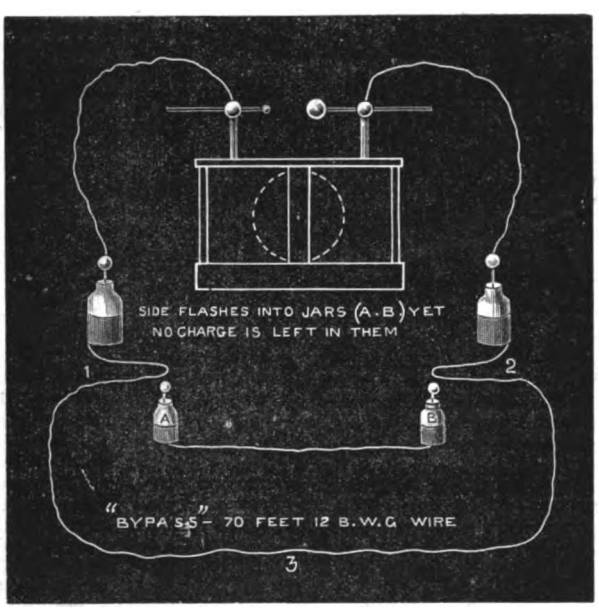
In conclusion, Dr. LODGE expressed his opinion that the Lightning Rod Conference did much good work, and regretted that he should have seemed antagonistic towards it.

The discussion was then adjourned to May 16.

THURSDAY, MAY 16TH.

Mr. WIMSHURST, on resuming the discussion, re performed his experiments on the difference in the protective power of points when the clouds are positive or negative, and said that in the latter case the point might be 2¼ to 2½ times as far away from the cloud as a dome and still protect. The reversal of the direction of the "B spark," by putting on a "bye pass," was also shown, together with experiments indicating that imperfect earth greatly increases the tendency to side-flash, and that this tendency is further increased by augmenting the size of the body receiving the flash and by connecting it to earth. In view of these facts the experimenter considered





The side flash at (1) is positive, and at (2) negative. At (3) the wire is normal, there being no side flash.—J. W.

[We are indebted to Mr. Wimshurst for kindly supplying us with diagrams, from which the above blocks were prepared. They are not in the authorised report.—ED. *E.*]

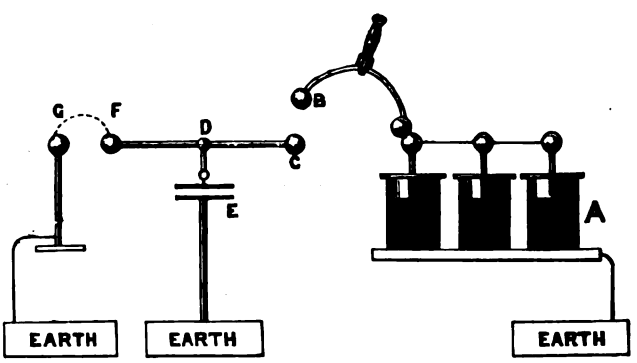
that the conclusions of Dr. Lodge, respecting the small importance of good earth and the propriety of connecting all pieces of metal together and to the earth, needed reconsideration. Side flashes were also taken by Leyden jars, and in some cases they were found unchanged when tested whilst in others the charge remained. An experiment, analogous to the sparking seen on the gilding of the walls during Dr. Lodge's experiments was next shown, in which sparks passed between separate pieces of foil forming a spangled outer coating of a Leyden jar when an insulated body within the jar was connected to an influence machine at work.

Prof. HUGHES said he did not agree with Dr. Lodge's statement that the "older electricians" never contemplated "case *b*," for Sir W. Snow Harris had recognised the difference, and from experiments made by Prof. Guillemin, M. Bertsch and himself, in an investigation on Lightning Protectors (see *Annales Telegraphique*, 1865, and *The Electrician*, July 13, 1888), it was concluded that Leyden jar discharges differed from ordinary lightning; for it was well known that protectors did protect instruments, whereas in their experiments with large jars nothing protected them. He also considered it unfair of Dr. Lodge to take all the credit of having recognised the distinction between cases *a* and *b* and the influence of self-induction to himself, altogether ignoring his predecessors in the field, for Prof. Guillemin showed that a sheet of tinfoil might protect an iron wire, whereas the same foil, rolled up like a wire, failed to protect.

As regards iron *v.* copper, his (Prof. Hughes') experiments prove that for rapidly-varying voltaic currents copper is decidedly superior, and the preference now given to copper for telegraphic and telephonic work points to the same conclusion. It had also been shown that iron wire was circularly magnetised by discharging a Leyden jar through it, and the production of this effect would, he considered, retard the discharge.

Mr. G. J. SYMONS thought Dr. Lodge did not realise the alarming nature of his own remarks in reference to the Rules of the Lightning Rod Conference; as a member of that body he was anxious to improve the rules wherever possible, but considered it injudicious to discard well-tried and safe rules until something better had been devised and tested by experience. As regards Points *v.* Knobs, the subject had been thrashed out 120 years ago. The Lightning Rod Conference had recognised the importance of hot-air currents, for they recommended that house conductors should be fixed to the kitchen chimneys. The dimensions of conductors was next referred to, and from the fact of large ones having been fused, the speaker thought Mr. Preece should not recommend small wire. He also stated that although the existence of a "protected area" around a conductor was disputed, yet much evidence pointed in that direction.

Col. ARMSTRONG, R.E., speaking of the protection of magazines, said he believed the War Office was the only body who had regular and systematic earth resistance tests made on their conductors. From his experience in the matter he could say that no accident had ever happened to a magazine whose conductors made good earth as shown by the regular tests, whereas several had occurred in cases where the earth was bad (say 200 ohms). In one case the conductor was fused below the point at which the main flash left the conductor, and this he believed due to want of continuity at the lower place. In another case cartridges packed in a sealed metal case were exploded by a lightning flash, thus showing that currents were not confined entirely to the outer layers, as Dr. Lodge supposes.



The above represents Prof. Hughes' original experiment of 1864, and is repeated from *The Electrician* of July 13, 1888.

Mr. A. J. I. ADAMS considered wires carrying varying currents to be under stress, and that such stress was relieved by radiation from the wire. The amount of this so-called radiation he takes to be a measure of the opposition offered to the passage of the current, and says that copper radiates about 25 per cent. less than iron or brass.

Mr. SPAGNOLETTI said telegraph wires were very seldom fused, although instruments were frequently damaged, and as an instance of such wires conveying large lightning currents, cited a case in which a lineman was killed by touching a wire which was struck by lightning at a point 50 miles away. He also asked whether lightning flashes had been proved to be oscillatory.

Mr. S. EVERSHED described some observations he made in 1877, which tend to show that the "B spark" does occur in nature. A thunderstorm was in progress about five miles from his place of observation, where he had a gold leaf electroscope and a quadrant electrometer connected to an insulated plate about 6ft. high. In the intervals between the flashes the leaves remained open about ¼in., but instantaneously with each flash they opened to three times that amount. The spot of light from his electrometer disappeared with such rapidity that he could never say in which direction it moved. These facts also show that "Nature" is not always "slow and solemn" as Mr. Preece would have us suppose, and the peculiar effects exhibited at Antwerp Railway Station prove that lightning does not always behave in accordance with the views of the Lightning Rod Conference.

Referring to Mr. Preece's supposed proofs from telegraphic records that flashes are not oscillatory, Mr. Evershed pointed out that such records would be produced even if oscillations were present, for a greater quantity of electricity passes in one direction than in the other.

The PRESIDENT (Sir W. Thomson), in closing the discussion, thought Dr. Lodge's Paper a most interesting and valuable one, and the Institution was greatly indebted to its author for bringing the matter so prominently forward. All admit that the importance of self-induction was not sufficiently recognised previously. He could not say whether Franklin knew of its existence, but Sir W. Snow Harris did, and many views held by the latter which until recently were condemned, have now been proved correct. Referring to § 56 in the Paper he thought Dr. Lodge did not mean what was

Digitized by Google

there stated as to the shape of section of the conductor, for it was quite certain that flat ribbon had much less self-induction than round rod.

As regards gas and water pipes as earth, Sir William considered that they made a good earth, and he did not see much danger in connecting pieces of metal with the lightning conductor in cases where no other earth could be obtained.

In view of Col. Armstrong's statement about cartridges being exploded when completely enclosed in metal casings, he thought it important to try if iron cases afforded more protection than brass or copper ones, for it was probable that the magnetisation of the iron by the currents would produce additional screening. Faraday's electric cage experiment should also be repeated, using the more sensitive apparatus since devised to search for any internal effect.

In conclusion, the President said the Report of the Lightning Rod Conference is a very important work, and though some flaws may exist, yet on the whole experience gives very strong reasons for believing that the rules are good.

BOROUGH OF BEDFORD.

REPORT OF THE ELECTRIC LIGHT COMMITTEE.

This Committee was appointed by the Council on November, 9th, 1888, to consider and report to the Council upon electric lighting. . . .

After some preliminary remarks with regard to the advantages of the electric light, and the success achieved at Taunton (which town was visited by the Committee), the report proceeds as follows :—

Applications have been received from the following companies to light this borough with electricity, viz. :—

The Bedford Electric Light Company (Limited),

The Anglo-American Brush Electric Light Corporation (Limited),

The India-rubber, Gutta Percha and Telegraph Works Company (Limited).

The Committee has no doubt that any of the companies named would perform the lighting effectually, but it is obvious that if a company can make a profit for its shareholders such profit can be secured to the ratepayers by the Corporation supplying the lighting at the prime cost. The Committee therefore recommends that the Corporation should retain the undertaking in its own hands.

In order that the Council might be in a position to form an opinion of the feasibility of establishing an installation with profit, the Committee has given considerable care to the question of carrying it out practically, and as the result has to offer the following observations :—

As to the motive power proposed to be employed, the Committee in the first instance directed its attention to the use of the water-power of the river. The Committee finds that this is altogether inadequate to meet all the requirements of the Borough, and therefore does not recommend its use.

The Committee having carefully considered the question of a site of the proposed works, is unanimously of opinion that a portion of the land belonging to the Corporation on the west side of the Cauldwell Bridge could be most advantageously used for the purpose. It offers the following advantages :—

From a station there erected both sides of the Borough could be conveniently served. As it adjoins the river the water supply would be convenient and cheap, and, if necessary, a siding to the railway could be connected for the purpose of the delivery of coal.

It is also a sufficient distance from any property likely to be annoyed by the carrying on of the business.

The Committee submit the following detailed capital and annual expenditure accounts, which are based upon reliable information from existing successful companies :—

Capital Account.

Building, including chimney shaft	£1,500
Three engines of 75 horse-power each, including boilers	4,500
Four dynamos	1,000
One hundred arc lamps, £20 each	2,000
Wire (7 miles)	434
Labour setting up	500
Two dynamos for incandescent lighting	1,800
Two engines and boilers	2,250
Miscellaneous plant, sundry expenses	1,016
	£15,000

Annual Expenditure Account.

Interest on £15,000 at 4 per cent.	£600
Coal	800
Depreciation	375
Carbon renewals	330
Labour and electrician	450
Rent, rates, taxes, and other sundry expenses	200
	£2,755

The capital mentioned would be sufficient to provide an installation of 100 arc lights, and leave sufficient power to supply 4,500 incandescent lamps for private lighting.

The Committee has prepared and marked upon the map the suggested position of the public lamps. The lamps will be of 1,200 candle-power each.

For the purpose of these calculations the Committee has worked out the interest to be paid on the capital at 4 per cent., though there is little doubt that the money can be obtained at a lower rate.

In accordance with the foregoing account the annual expenditure will be £2,755

Estimated to be received from—

Incandescent lamps, 4,500 at 10s. each	£2,250	
Do. from churches, chapels, &c.	200	
		2,450
Net cost of lighting with electricity the area described		£305

The last two half-yearly payments for lighting with gas amount to £1,437. This amount is considerably increased every year, but it is taken for the purposes of comparison.

By the adoption of 100 electric lamps in the positions indicated 228 gas lamps would be displaced, the cost of which per annum is as follows :—

	£	s.	d.
Special lamps	93	17	0
Ordinary lamps at £2. 6s. 3d.	504	2	6
Police lamps extra	51	10	0
Representing an annual cost of	£649	9	6

The following figures will afford a comparative estimate of the relative lighting power of the two systems :—

100 electric lamps proposed to be introduced	= 120,000 candles.
228 gas lamps proposed to be displaced	= 4,000 candles.
Gain in lighting power	116,000 candles.

By the adoption of the electric light there will also be an immediate clear gain to the borough of about £345 per annum.

The committee has been most careful to place a moderate estimate upon the receipts for private lighting. It is quite certain that this profitable part of the business could be extended without any considerable increase of capital, and to such an extent that the Corporation may with confidence look forward to the public lighting being provided free of cost to the ratepayers. The committee confidently expects that the whole of the incandescent lights estimated for would be taken up as soon as they could be supplied, tradesmen especially being anxious to have the advantage of the light, both to avoid the damage now done to their goods by gas, and for other obvious reasons.

The committee recommends that it be empowered to take such steps as may be advised to obtain powers under the Electric Lighting Acts, and also to employ an electrician to advise as to the establishment of the proposed installation.

DETERMINING THE STRENGTH OF LIQUIDS BY MEANS OF THE VOLTAIC BALANCE.*

BY DR. G. GORE, F.R.S.

This method is based upon the circumstance that the greater the degree of concentration of a solution the larger is the amount of dilution required to reduce its voltaic energy to a given magnitude.

In a research on the "Relative Amounts of Voltaic Energy of Electrolytes"† (Roy. Soc. *Proc.*, Vol. XLV., p, 268), I have described the method of measuring the voltaic energy of a substance, and have given the magnitudes of such energy excited in a voltaic couple of unamalgamated zinc and platinum, by upwards of one hundred different substances when dissolved in water, in relation to that excited in the same couple by water alone, all the liquids being at atmospheric temperature.

In the present research, as examples of the applicability of the voltaic balance to determine the degree of concentration of liquids, I have taken aqueous solutions of nitric acid, hydrochloric acid, sulphuric acid, common salt, ammonia, and carbonate of soda, and ascertained the degree of strength of each by chemical analysis, by specific gravity, and by the voltaic balance method. The following numbers represent the proportions of water which were required by one part by weight of each of these substances in order to reduce its voltaic energy to the same magnitude, viz., to that required to just visibly move the needles of the galvanometer, and they therefore also represent the relative magnitudes of voltaic energy of the substances indicated by the respective formulæ.

						Temperature.	Average energy.
HCl.	Between	9,300,000	and	9,388,185	at	16·5°C.	9,344,092
H^2SO^4.	,,	3,690,476	,,	4,111,446	,,	19· ,,	3,900,941
HNO^3.	,,	3,039,215	,,	3,369,565	,,	19· ,,	3,204,395
NaCl.	,,	190,570	,,	221,428	,,	15· ,,	207,589
Na^2CO^3.	,,	−14,090	,,	−15,550	,,	19· ,,	−14,795
H^3N.	,,	−281,818	,,	−313,765	,,	15· ,,	−297,791

In each example given a known volume of solution was taken, and the proportion of substance in it was found by ordinary chemical analysis. A second portion was taken, its specific gravity ascertained by the method of weighing, and its degree of strength found by aid of the ordinary published tables of specific gravity. A third

* Read before the Royal Society, May 9, 1889.

† See also *Electrician*, April, 5, 1889, p. 626.

Digitized by Google

portion of known volume was then taken, its average amount of voltaic energy measured, and its degree of concentration found by the amount of dilution required to reduce its energy to the same magnitude; the less dilute it was at starting the greater the amount of dilution required. The following are the results :—

By	HCl.	H^2SO^4.	HNO^3.	NaCl.	Na^2CO^3.	H^3N.
Chemical analysis .	1·85	5·60	2·97	9·13	7·21	1·05
Specific gravity ...	1·70	5·44	2·80	8·74	7·63	1·03
Voltaic balance ...	1·65	5·70	2·90	8·71	7·57	1·06

The variations in the numbers are partly due to inequalities of temperature.

A much less quantity of substance is usually required by the voltaic balance method than by either of the others, and the operation is very quickly performed.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 11, 1889.

One of the most important electrical events of recent occurrence in this country is the action taken by the Boston Board of Aldermen in granting unanimous consent to the application of the West-End Railway Company, for power to establish and maintain a single trolley overhead system on each and all of the streets, squares and thoroughfares in the City of Boston, where it is already operating. This is a momentous decision, for it simply means that if the plans of the company are carried out in their entirety Boston will have at least 300 or 400 miles of electric railway service using overhead conductors. As I have already noted in this correspondence, the Board of Aldermen as well as the State authorities have been investigating the subject for some time past. While the success of the conduit system put down in Boston has not been, it is claimed, very great so far, the Sprague and Thomson-Houston overhead systems have been running with most creditable regularity and efficiency. It is asserted that it has not been particularly the desire of the West-End people to make a brilliant success of their conduit system, for the reason that they prefer to operate by the overhead method, and did not wish to have the practicability of the conduit system or the storage battery system urged against them.

With reference to electric railway operation, it is interesting to cite the figures of the Cambridge division of the West-end Street Railway operated by Thomson-Houston motors with overhead trolley connection. It appears that during the month of April eight motor cars ran 17,680 miles, and the cars they towed 19,149 miles. The number of round trips of motor cars was 2,720, and but seven trips were lost. This is an improvement even over the previous record, when the cars lost but nine trips out of 1,179. The service is very popular with the people, and the cars are crowded.

It may be noted, while on this subject, that there is now a great deal of agitation in various places where electric railways are going in on the point whether the overhead wires shall be single, using the rail as a return circuit, or whether the companies shall be compelled to put in complete metallic circuits involving the use of double trolleys. The electric railway companies naturally prefer the single trolley system, on account of its simplicity and greater cheapness, but in several places the telephone people have conducted an active warfare against the single trolley, urging that the rail return seriously affects the efficiency of telephonic communication. On the one hand the telephone companies urge that the street railways ought to have complete metallic circuits, and on the other hand the street railway people urge that the telephones all ought to have metallic circuits. While no decisive settlement of this dispute is to be expected, we shall very likely see the provision insisted on here and there that the complete overhead metallic return shall be used on the new roads. It is worthy of note, however, that this has not been insisted on as one of the conditions in Boston, but I expect we shall hear of considerable opposition in that city from property owners and others, who imagine themselves to be injuriously affected.

Recently, at the meeting of the Beacon Society in Boston, the subject of electrical development was discussed, more particularly as related to electric light and power. One of the speakers of the evening was Mr. C. A. Coffin, the Vice-President and mainspring of the huge Thomson-Houston Company, In the course of his remarks Mr. Coffin said that during the last seven years the Thomson-Houston Company had organised nearly 500 local electric light and power companies, and that less than one per cent. had got into any financial embarrassment, while not one in the 500 had failed to pay its obligations in full. Moreover, the growth of these companies in the use of arc lights showed an increase of from 1,500 lights six years ago to between 50,000 and 60,000 at the present time. It may be that here in America we are given to exaggeration and "high falutin," but I take it that it is simply impossible to exaggerate the importance and significance of such a wonderful growth as this. At the Electrical Exhibition in Philadelphia, in 1884, the Thomson-Houston system was first practically introduced to the public notice in a striking way, but its two great rivals, the Brush and the United States Companies were already in possession of large portions of the field, and had vigorous subcompanies in operation all over the country. Hence the work of developing the new system was doubly difficult, and yet, as we have seen, the excellent apparatus and the skilful management were equal to a development like that above referred to, of his share in which Mr. Coffin spoke so quietly and modestly. Mr. Coffin made the statement that the Thomson-Houston system was being extensively introduced into Japan, and that his company were doing business in Europe, in South America, in Australia, Australasia, Canada, the West Indies, and other parts of the globe. He went on to remark that there are in Massachusetts to-day more electric light plants than in the whole of Europe. He found Italy to stand at the head of European nations, while in England, owing to the fact that so many gas works are owned by the town and the city authorities, the process of introducing the electric light is extremely slow, and attended with many difficulties. It was natural that Mr. Coffin should make reference to the work that his company is now doing in the matter of electric railways. He said they had found as the result of all their work—and they had already had a great deal of experience—that the cost of electricity does not exceed 60 per cent. of the cost of animal power, while on all the roads where electricity has been adopted there is a marked increase of traffic and patronage. One of the roads recently started, for example, shows receipts four times as great with four electric cars as they were with five cars run by horses. Mr. Coffin's statements as to electric lighting and electric railways were well supplemented by those given by Mr. Jenks, who spoke for the Edison system, and who said that the Edison Company now had in this country 200 stations and 1,525 isolated plants, with a total dynamo capacity of 1,126,000 lamps, which, of course, is far short of representing the number of lamps actually wired up to be run on those plants.

An invitation has recently reached this city from the Board of Trade of St. John, New Brunswick, with regard to the Exhibition which is to held there in the coming July. The Exhibition is planned in connection with the carnival celebrating the union of the cities of St. John and Portland and their looping into the system of the Canadian Pacific Railway. It is proposed to make the Exhibition largely electrical, and it is hoped and believed that the American manufacturers will be well represented. There is a fair quantity of American electrical apparatus now sold in that part of the Dominion, but it is believed that the full extent of the market has not yet been anything like realised. Of course, if there were reciprocity of trade between the two countries there would be no difficulty in doing a very large business; but even as things are now not a few opportunities present themselves. I do not know whether English manufacturers and concerns have been invited, but it is not to be lost sight of that the North American Colonies are naturally our customers for a large part of their electrical apparatus. I believe Montreal is the centre of what electrical manufacturing there is in Canada, but, as far as I can learn

Digitized by Google

the output is not very large, and hence the cost of production remains high.

I noted the fact not long since that the Thomson-Houston people, at their Lynn factory, had been treating their motors to baths of cold water, and had found that as now constructed they would stand any amount of exposure and rough usage of that kind. Mr. S. D. Greene, of the Sprague Company, now comes out with a letter in the papers giving details of some very interesting experiments of like nature, but of earlier date, made at the Sprague Factory. An armature after having been treated in some method devised by Mr. Sprague was allowed to soak in a barrel of fresh water for 24 hours. It was then soaked for another 24 hours in a barrel containing a strong saline solution. It was next taken out and put into a machine and run for two and a-half hours on an overload of $33\frac{1}{3}$ per cent. At the end of this run the motor was tested and was found to be as sound as it was when the experiments began. It may seem to English electrical engineers that these little tests are perhaps mere showy *tours de force*, but those who are familiar with the conditions that often obtain on the American street railways well know that very often, especially in new communities or in growing suburbs, roads are none too well constructed, and hence the motors under the cars are exposed to serious danger from the seas of mud and dirty water through which they have to pass. I have myself been out on electric cars running for well nigh a mile together on tracks that were out of sight under the chilly and dirty accumulations of a spring thaw, where the snow had been two or three feet deep, and where the road bed had consisted of little but a made soil.

Another step has been taken in the direction of carrying out the New York State law for the infliction of the death penalty by means of electricity. Mr. Harold P. Brown, who has been so prominent in connection with all the experiments on the lower animals with the alternating current, has now made arrangements with the Superintendent of State Prisons to furnish him with three Westinghouse alternating machines, each having an E.M.F., it is said, of 1,000 volts. It would appear that Mr. Brown has secured this apparatus through some third party, so that the Westinghouse Company did not know the purpose for which it was to be used, and very sharp comments are made in some quarters on the necessity of resorting to such a subterfuge. It is said that the current will be passed through the victim by means of an electric cap made of metal covered with sponge, which will go on his head, and by a heavy pair of tightly-laced shoes with sponge inside which will go on his feet. After the electroded convict has been strapped into an open chair and fitted with his electrical cap and electrical shoes, the warden of the prison closes the circuit, and he is "electrosized" or "thanatopsied," or "electrocuted," or "electrogerried" in about 15 seconds. It was expected that all the electrical executions would have been carried out at one place to avoid mishaps, trouble and expense, but it would seem that the apparatus is to be put in at three different State prisons, Auburn, Clinton, and Sing Sing.

Some idea of the interest taken in electricity in educational circles is given by the announcement that Princeton College is now to establish a course of electrical engineering. Princeton is situated in New Jersey, not far from this city. It will be remembered that Columbia College here is also about to establish a post-graduate course in electrical engineering; and as we have Stevens Institute just across the Hudson river in Hoboken, and Cornell University in the northern part of the State, to say nothing of Harvard and Yale within hailing distance in New England, and the University of Pennsylvania and John Hopkins University to the south of us, it will be seen that the facilities for electrical training and study are rapidly multiplying themselves, and that there should therefore soon be no want of very well-equipped young electricians for all branches of electrical science and industry.

Stockport.—Steps are being taken in this town to form an electric lighting company.

CORRESPONDENCE.

BRITISH ASSOCIATION LIGHTNING ROD DISCUSSION.

TO THE EDITOR OF THE ELECTRICIAN.

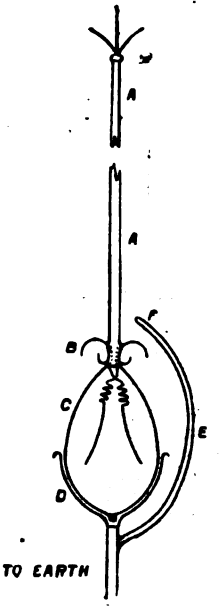
SIR: I have just seen what purports to be a report of the lightning rod discussion at Bath, as published in the annual volume of the British Association. Its appearance in that volume may lead readers to suppose that it is a corrected and authorised report of what was said. So far as I am concerned this is certainly not the case, and it bears evidence of being practically unedited. Speaking for myself, I find I am made to talk a lot of nonsense, and occasionally to say things the exact contrary of what I could have intended. I judge that the same thing applies to others, but for myself I write to disclaim all responsibility for the production.—Yours, &c.,

OLIVER J. LODGE.

LIGHTNING PROTECTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Seeing the discussion *re* Lightning Conductors, and having experimented some two years on disruptive discharges, I should feel obliged if you would insert the following description of a contrivance I devised in the early part of last year, and which I think might prove useful in the dissipation of electric energy besides. I should much like to know the opinion of some of your readers on the matter.



AA is a lightning conductor or its equivalent, B an oil insulator through which the conductor passes into a large glass bulb C, which has previously been exhausted by means of a high vacuum pump, and in which is contained two metal strips of aluminium after the style of an electroscope, which are connected to the conductor, where it passes into the bulb, by circular springs; towards the bottom on the outside of bulb is a thin metal cup full of oil D, in connection with the earth, from which projects a side conductor E, which terminates at its upper end with a point F, nearly at right angles to A.

On any electrical excitation of the conductor A the metal strips diverge and give up their charge to the attenuated vapour condensed on the inside of sides of bulb, which produces a counter excitation on the metal cup D, and which eventually culminates in a spark from A to E, and so lowers the potential of A, and, therefore, the source from which A derives its energy.

This simple device with a few modifications seems to me to answer equally well either as a lightning arrestor or as an ordinary condenser.

In the actual experiments made by me I used a large Edison lamp with a broken horse-shoe filament, which answered every requirement; and I found that Leyden jars so made had a much

Digitized by Google

greater insulation and a larger capacity than the usual jars constructed for electrical discharges generally, besides costing little to make, as large users of incandescent lamps are willing (or at least were good enough to do so in my case) to give a choice out of a large number of broken or disused lamps which are of no use to them. Leyden jars so constructed are very useful for obtaining a brush discharge only if the vacuum is very high, as they gradually give up their charge and do not spark; by a suitable and careful choice of lamps a Leyden jar battery can be made to give either a quick, slow, or brush discharge, and this depends, as far as I can judge, on the degree of residual vapour in the bulb.—Yours, &c.,

May 18, 1889. ALFRED TREEBY.

MR. HAROLD BROWN AND THE WESTINGHOUSE SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As the Westinghouse Electric Company are making strenuous efforts to introduce their apparatus, and are urging in its favour its "economy" as well as its "safety," and as I am frequently consulted on the subject, I felt authorised to address to Mr. Westinghouse, on the 4th of April, a registered letter, a copy of which I enclose, giving him a fair opportunity to have his remarkable claims demonstrated at my expense. The official receipt for the letter has long since reached me, but there has been no reply. You will remember that Mr. Westinghouse and his experts pronounced this current "safe" and "harmless," and that they have violently attacked the writer for maintaining and proving that it was dangerous. As a result of my work, the New York State authorities, after a long and thorough investigation, have purchased for electrical execution three Westinghouse alternating-current dynamos, built for electric lighting. Having thus proved my point as far as the danger of the apparatus is concerned, I am anxious to have its commercial value definitely settled by the proposed test. I would, therefore, be glad to receive from you any suggestions concerning methods, or any results of your experience with the alternating current that you may care to place at my disposal. In return I shall take pleasure in sending you copy of report of the tests when completed.—Yours, &c., HAROLD P. BROWN.

[COPY.]

DEAR SIR: The public admission made at Hamilton by Mr. Stillwell, your electrician, that he knew of at least three men killed by the Westinghouse alternating current which you have pronounced safe, and the adoption of the same current by the State of New York for electrical executions, are sufficient reasons for your failure to accept my challenge of December 18, 1888. I then offered to take the continuous current from hand to hand to prove what you deny, if you would take the alternating current at the same pressure and for the same number of seconds. You did not dare to risk your life to prove the sincerity of your statements concerning the safety of the Westinghouse alternating current. Will you now dare to risk your money to substantiate your claims as to the efficiency of the Westinghouse alternating-current system?

If so, I hereby give you an opportunity to sell another electric light station (with 650 lamps of 16 candle-power each), and obtain an extensive advertisement at my expense.

You have asserted for many months, both by representations of yourself and agents and by authorised advertisements in electrical and other papers, that "50 per cent. more light from a given expenditure of power (fuel)" is guaranteed by the Westinghouse Electric Company than can be obtained by any continuous ("direct") current system.

If it is possible to convert force from one form into another, and gain 50 per cent. in the operation, your company has made the most wonderful discovery of modern times, which, carried to its logical conclusion, will give us perpetual motion by a series of conversions from high to low tension, or the reverse.

To substantiate this remarkable claim I challenge you to send a complete 650-light Westinghouse alternating-current plant, with not less than thirty converters, to the Electrical Testing Bureau of the John Hopkins University, to be there installed by your own experts, and left for a three months' test. I will send a plant of the same capacity of the Mather, Schuyler, Jenney or Thomson-Houston continuous-current apparatus.

The electricians of the Bureau shall then determine the efficiency of the dynamos from one lamp only to full capacity by dynamometer; the efficiency and life of lamps and efficiency of converters under full load, half-load, a single lamp on each converter, and with secondaries open. The apparatus supplied to be standard commercial make, and burned-out lamps not to be replaced. At the end of the tests the Bureau's reports to be published, and if the Westinghouse alternating system gives 50 per cent. more light from the same expenditure of power, or proves to be that much more economical in running expenses, then I will pay all expenses of tests of both apparatus and will purchase your plant at list price to present to the University.

If your apparatus fails to give 50 per cent. more light from the same expenditure of power, then you are to pay all expenses of the tests of both apparatus and to purchase the continuous-current apparatus supplied by me at list price and present same to the University.

If you claim that the remarkable advantages of the Westinghouse system are due to the use of the Westinghouse engine, which has so extensive a sale and is so highly recommended by your company, you can use it in the test, and I will arrange to operate against it some one of the standard high-speed automatic cut-off engines.

If my challenge is accepted each apparatus is to have one expert in attendance, but he is not to be permitted to interfere with the machinery in any way, or to take part in any of the tests.

If you fail to accept this challenge within a reasonable time, and are disinclined to have the value of the Westinghouse Electric Company's guarantees publicly established, I shall feel at liberty to personally submit your apparatus to the Bureau for an efficiency test, and shall publish their report.—Sincerely yours,

HAROLD P. BROWN, Electrical Engineer.

45 and 47, Wall-street, New York, April 4, 1889.

Geo. Westinghouse, jun., President Westinghouse Electric Company, Pittsburgh, Pa.

[Some interesting remarks on this subject will be found in our "American Notes" this week.—ED. *E.*]

PATENT RECORD.

APPLICATIONS FOR PATENTS.

April 27, 1889.

7,023. R. SNOWDON. Manchester. Improvements in electric meters.

7,037. W. BLYTH. Glasgow. Improvements in electricity meters.

7,038. W. BALCH. London. Improvements in electric battery cells for lighting or for other purposes.

April 29, 1889.

7,088. R. SNOWDON. Chesterfield. Improvements in electric measuring instruments.

7,127. G. E. VAUGHAN. London. Improvements in or connected with the brush contacts of electric railways (S. Trot, Nova Scotia).

7,129. A. J. HOWES. London. Improvements in arc electric lamps.

COMPANIES' MEETINGS & REPORTS.

Woodhouse and Rawson (Limited).

Lieut.-General Sir JOHN STOKES, K.C.B., presided at the Cannon-street Hotel, on the 17th inst., over an extraordinary general meeting of the shareholders in this company.

The SECRETARY (Mr. J. SHURMER) read the notice convening the meeting.

The CHAIRMAN then said: Gentlemen, I have much pleasure in meeting you again and in being able to put before you not only very satisfactory results but also good prospects for the future. With regard to the general business of the Company, the advance in the electrical work that I mentioned at the meeting in December last has continued, and during the last few months there has been a great extension of electrical enterprise in all directions. Our business is steadily progressing, and we are glad to say that with regard to our installations the really good work we do is fully appreciated. When we consider the large amount of central station work that is being done, not only in London (twenty-one central stations), but in other parts of England and the Continent, the outlook is very encouraging. With regard to the contracts on hand for the maintenance of installations, owing to the good quality of the work done and material supplied we find the maintenance is costing less than we originally anticipated, and is giving general satisfaction. Our general business has steadily increased outside of electrical work, and we have taken out and acquired several valuable patents, chiefly electrical, during the past year. Abroad there has been a gratifying and rapid increase in our business, and I am happy to announce that we have just satisfactorily carried through an important negotiation, whereby we make a large profit, and we also have made arrangements whereby we secure the supply of considerable quantities of the various goods required by several leading electrical companies. With regard to the Elmore patents, in which we are interested, the Elmore Patent Copper Depositing Company, which I mentioned at the last meeting, has been successfully brought out, being subscribed for nearly four times over, since which we have put up a plant abroad, and more than proved the statements that were made as to the value of the process. The trials were witnessed by some of the most experienced men in the copper industry, and proved thoroughly satisfactory on every point. I myself saw some articles being made and the experiments going on, and noted the great surprise of the technical men at the very high quality of the copper, and the extraordinary results, they acknowledging the low cost of manufacture, the high quality of the articles made, and the other advantages. I may mention that the workman employed actually refused at first to make the experiments with the copper as requested, being, as he said, certain of failure, but which proved easy and perfectly successful. In fact it is now undoubted that this is one of the most important of recent discoveries, and it is very gratifying that it has fallen to this Company to secure its development. With regard to the amalgamation and sale to the new Company, this is on the lines approved of by the last meeting, viz., that you receive now your dividends up to the 30th June last, together with a bonus of 10 per cent. upon the amounts paid up on your shares from the new Company, and besides this, certain assets are to be distributed amongst you. It is expected that these will amount to a substantial bonus, and that as the new Company takes over the businesses from fixed dates as going concerns, it will be in a position to pay a considerable interim dividend in July next. The Directors have not taken this step without mature thought and deliberation, and as they themselves hold more than a tenth of the whole capital of this Company, you may rest assured that it is in the interest of the shareholders. The scheme has also been approved by most of the large shareholders. I may say that the new company will be a strong, compact organisation, with a first-rate board and the same supervision and staff as we have now, together with the advantages of the staff from the other companies. From its constitution, which is an amalgamation of manufacturing, supply, and installation interests, it will be capable of efficiently undertaking not only almost every description of electrical work, but the large contracts that are expected. As you are aware, at present the major portion of the profits, after paying 10 per cent., goes to the holders of the Founders' Shares. By the sale to the new company these shares are done away with, thus enabling us to pay larger dividends than before. The dividend now declared makes 12 per cent. for the year. Satisfactory as this is, I may say that from earnings already made by the companies to be amalgamated the new company will be in a position to pay in July next a dividend at a still higher rate, and we anticipate a considerable demand for the shares, the issue of which will take place almost immediately. He concluded by moving a resolution for the adoption of the accounts and the payment of the dividend mentioned.

Mr. LAMBERT seconded the motion.

In answer to Mr. FELLOWS,

The CHAIRMAN stated that the new Company would take over the undertaking of Woodhouse and Rawson from January 1st this year. The motion was then put and carried. Continuing, the Chairman proposed:—

"That the agreement, a draft of which has been produced to this meeting and initialled by the Secretary, is hereby approved, and the Directors are hereby authorised to enter into the same and to carry the same into effect."

The general conditions of the agreement he had sketched to them in what he had stated.

Mr. RAWSON then went through the clauses of the agreement, which provided that the vendor company should sell and the purchasing company should buy, as from January 1st last, all property of Woodhouse and Rawson (Limited) with the exception of the latter's interest in certain assets, which were going to be distributed among the shareholders, and also with the exception of the book debts due to and by the vendor Company. The consideration for the purchase was to be £200,500, being 7,700 Ordinary shares, 600 Preference shares, and £20,000 in Debentures. That was arranged, Mr. Rawson pointed out, so that they might get a Stock Exchange quotation in the new Company. The largest amount was taken in the Ordinary and Preference shares and Debentures of the new Company that was allowed, and the result of that was that the shareholders of Woodhouse and Rawson would have to take a certain amount of cash, to be arranged afterwards by the liquidator. A certain amount of cash was to be paid in seven days, and the remainder was to be paid as the properties were handed over. The shares in the new Company were to be issued fully paid. The new Company was to adopt, fulfil and perform all contracts binding on the old Company, and was to keep the old Company indemnified against liabilities. From the beginning of January, 1889, the new Company should be deemed to have carried on the business of the old Company, and the profits made since January 1st (which amounted roughly to £20,000) were to be taken over by the new Company. The old Company was to take all the necessary steps to give effect to the agreement.

A SHAREHOLDER said he believed that at the last meeting the Chairman stated that the shareholders would not be expected to take shares in the new Company, but that they could, if they thought proper, take cash for their original shares.

The CHAIRMAN: That will be so if the Company is satisfactorily launched.

Mr. RAWSON: When the Company is satisfactorily launched, no doubt that will be so. The present arrangement is that we shall get a large amount of cash, quite sufficient to more than pay out any shareholder who wants to be paid out.

The SHAREHOLDER: It was stated definitely at the last meeting that that would be so.

The SOLICITOR: It is a right to every shareholder.

Colonel PATTEN seconded the motion, which was then put to the meeting and carried unanimously.

The proceedings then terminated,

Elmore's Patent Copper Depositing Company (Limited).

The statutory meeting of this Company was held on the 17th inst. at the City Terminus Hotel, Cannon-street, Sir John Morris, K.C.S.I., in the chair.

Digitized by Google

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN said that the whole of the issue of shares in the Company had been allotted. A suitable site for the conduct of their business had been obtained near Leeds, most conveniently situated on the Aire and Calder Navigation Canal on the one side and the Midland main line on the other. The rates for the delivery of raw material to the works and for the despatch of manufactured goods could hardly be more favourable than they were in respect of these works. The management had been arranging to obtain tenders for the erection of suitable buildings, &c., and the contractor had already commenced the erection of the same, and had undertaken to have them completed by the end of June. Orders for the necessary plant and machinery have also long since been placed, and will, so far as they could see, be ready for delivery by the time our buildings are ready to receive the same. Some preliminary tests and experiments had been carried out under the immediate and careful supervision of the managers, and some tubes produced which, upon testing, had yielded the most gratifying results; and, so far as it is allowable to judge of the process from this small scale, there can be no reasonable doubt that the process is as valuable and profitable as was foreshadowed in the prospectus issued to the public. Some of these tubes were in the room that day for examination, and what makes these more noteworthy is the fact that the plant used in their production was of a somewhat obsolete character, and not so reliable as that about to be installed at the new works. A most satisfactory report had been received in reference to these experiments. It was also very satisfactory to know that the rise and fall in the price of copper did not materially affect the prosperity of the Company, though, of course, the lower the price of copper the larger the business likely to be done. Four additional members had been elected to the Board since the promotion of the Company, viz., Mr. F. L. Rawson, of Woodhouse and Rawson, Limited, whose technical knowledge is most valuable to the Company; Mr. G. C. V. Holmes, and Messrs. J. J. Atkinson and J. T. Cooper, the two latter gentlemen being the representatives of the vendors. The Company's managers, Messrs. F. E. and A. S. Elmore, were busily engaged in connection with the erection of the works and installation of the plant, and trial tests already referred to were carried out under the supervision of these gentlemen.

General LIGHT said he saw Mr. Stepney Rawson present, and he believed he had been in France, and had seen the working of the process. He thought any information he could give them would be interesting.

Another SHAREHOLDER said he noticed that a certain firm were making arrangements to carry on the system on a royalty. He should like to know if they were carrying it out.

The CHAIRMAN said: Until they had their own works, and could see the results, they thought it better to defer the conclusion of the negotiations.

Mr. F. L. RAWSON said he was not aware that there were any tubes in use in boilers. This company was not so much engaged in cheap work, such as boiler tubes, but more in the manufacture of larger things. He might say that he had a statement of the amount of copper likely to be used, by one of the officials of this company, and the figures were something enormous, a long way more than himself and the other members of the Board thought was possible. A tube 12-in. in diameter, solid-drawn, cost 3s. a pound to make, and they thought they would be able to make them for 2d. or 3d. a pound; so that there was no use their going into the manufacture of boiler tubes when there were numbers of articles which cost a great amount of money, and could not be made except by the Elmore process.

Mr. DICKINSON asked what was being done with regard to steam pipes.

Mr. F. L. RAWSON said it was very unfortunate that Mr. Elmore, the father of their Managing Directors, was ill and unable to leave his bed. He could, however, say that the large steam pipes had been fully tested by well-known firms in the copper trade, who all agreed as to the extraordinary quality of the copper. Several of them had told him that they had no idea it was possible to make copper of that quality at all. Not only did they intend to make the large pipes, but there was a large demand for copper platings, which were now made in large quantities, and that was one reason for changing their works, so as to be on the direct main line of the Midland Railway.

Mr. STEPNEY RAWSON said some months ago, before the Company was brought out, he had certain figures brought before him as the result of previous trials made by Mr. Elmore and his sons. On examining them he was unable to find any flaw, but his verdict was they were too good to be true. When it became his business to go and examine into these trials he went to pick holes in the process, if he could find any, but he was as unable to find any holes in the process as he was to find fault with the previous figures. The more complete trial extended over ten days. They were working night and day, and a great part of the time he was actually present, till the simplicity of the process began at last to pall upon one. There was absolutely nothing to do except to keep the engine going; the rest of it was purely automatic, and became rather wearisome from its absolute simplicity. The keynote was no doubt the burnishing. It seemed a small difference from doing a thing without rubbing and doing it with rubbing; but that was the key to the whole process. Now, it might occur to some of them that he was speaking only as an electrician, and that would be perfectly justifiable; but he saw there many technical and practical authorities on copper working, who were as much astonished as he was: commencing with absolute doubt of the possible result of the statements, proceeding from that to incredulity, and at last winding up with confident belief. The proofs were on their own machines, attended by their own workmen; and there was no possible better proof than to see a practical man start with the idea that a certain thing could not be done, and then for him to find that he could do it himself. That he saw on many separate occasions, and from the more technical to the practical man at the finish there remained nothing but one implicit belief in the value of the process. It became necessary at the end of the tests to invent more stringent tests than ordinary copper was usually put to. These tests were invented by people who were looking into it, and many of them were proposed ironically. The results of these tests were absolutely successful, leaving over and above what they had proposed a very considerable margin, making it possible to put the copper to still further tests than they had ironically proposed. One test was submitted to a large meeting of the most capable authorities on copper in the world, and the next day it was carried out, with the result that perhaps the greatest authority in the world expressed himself absolutely satisfied and a thorough believer in the process. From the practical side of the question there could be no doubt of the value of the process. (Applause.)

The CHAIRMAN thought their very best thanks were due to Mr. Stepney Rawson for the information he had given them.

A vote of thanks to the Chairman closed the proceedings.

Submarine Cables Trust.

The following is the report of the Trustees for the financial year to the 15th April last, to be presented at the eighteenth ordinary annual meeting of the certificate holders, to be held at the offices of the Trust, 50, Old Broad-street, E.C., this day (Friday) at three o'clock:—

The revenue for the period, including the balance brought from the previous accounts, viz., £1,448. 5s. 5d., amounted to £20,567. 3s. 7d. The coupon due on 15th April, 1888, was paid in two instalments, viz.—£2. 10s. on 15th October, and the balance of 10s. on 15th November last. £2. 12s. 6d. of the coupon due 15th October, 1888, was paid on the 15th April last. The balance of 7s. 6d. will be paid on the 15th inst. The expenses of the Trust amounted to £1,383. 19s. 7d., and the

payments on account of the coupons to £19,018. 2s. 6d., together £20,402. 2s. 1d., leaving a balance of £165. 1s. 6d. to be carried forward. A table showing the original and present investments of the Trust is appended to the report. The meeting will have to elect two auditors for the current year; Mr. John G. Griffiths and Mr. John Gane offer themselves for re-election.

Consolidated Telephone Construction and Maintenance Company (Limited).

Report for the year ended March 31, 1889, to be presented at the eighth annual general meeting of the Company, to be held at the Cannon-street Hotel, London, E.C., on Thursday, the 30th inst., at 12 o'clock :—

The accounts show a net profit of £11,914. 4s. 3d., which, with the amount carried forward from last year, leaves a balance of £13,286. 14s. 2d. for disposal, after making provision for doubtful debts. The Directors propose to deal with this amount as follows, viz.: to pay a further dividend of £7 per cent. for the half-year, making with the interim dividend paid in November last, £6 per cent. for the year; writing off the sum of £520. 4s. 6d. for depreciation of plant, machinery and furniture; and the sum of £2,000 from goodwill, patent rights, &c., thus leaving a balance of £1,568. 17s. 7d. to carry forward.

During the year the Directors have received a further sum of £3,044. 18s. 6d. on account of profit arising from the liquidation of the River Plate business, which is included in the above statement, and there is still a balance to be received under that head.

The action in Belgium in relation to the patents, in which the Edison Gower-Bell Telephone Company of Europe is interested, is now in the hands of experts, to decide whether the instruments used in Belgium are infringements of the Edison patent. It is difficult to see how they can decide otherwise, as the law courts of England and the United States have repeatedly decided that they are infringements.

Your Directors are pleased to state that the working of the factory under their direct management has proceeded very satisfactorily, with the results as shown in the balance-sheet.

The relations between the United Telephone Company and this Company continue to be of an amicable nature, and your Board are glad to report that increased orders have been received during the past year from the Managing Director of that Company. The subsidiary companies continue to make most satisfactory progress, as is shown by the following statement :—

	Year ended March 31.					
	Subscribers.		Rental.		Increase.	
	1888.	1889.	1888.	1889.	Subscribers.	Rental.
			£	£		£
Telephone Co. of Austria	2,036	2,441	13,483	15,588	405	2,105
Anglo-Portuguese Telephone Co...	1,500	1,713	9,772	11,077	213	1,305
Total increase for the year.....					618	£3,410

For some time your Board have had under consideration the necessity of finding working capital for the subsidiary companies. With this object in view it will be seen that notice is now given for taking the necessary legal steps to carry out this proposal, and the attention of the shareholders is called to the prospectus accompanying the report relating to the subject.

In accordance with the Articles of Association the following Directors retire by rotation, and being eligible, offer themselves for re-election, viz.: J. H. Buckingham, Esq., and Richard Van Zeller, Esq.

The auditors, J. G. Griffiths, Esq., F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and A. E. Green, Esq., F.S.A.A., also retire, and offer themselves for re-election.

An extraordinary general meeting will be held immediately following the ordinary general meeting, when the following resolutions will be proposed :—

"*That the capital be increased to* £307,545 *by the creation of* 75,000 *new shares of* £1 *each.*"

"*That the new shares be called Preference Shares, and that the holders thereof be entitled to a preferential dividend at the rate of* £6 *per cent. per annum, payable out of the profits of each year without any right in case of deficiency to resort to the profits of subsequent years.*"

"*That the holders of the said Preference Shares shall be entitled on any distribution of the assets of the Company to be repaid in the first place the amount paid up on the Preference Shares held by them respectively, before any payment out of such assets to the other members of the Company.*"

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 17, 1889, amounted to £4,932.

THE MEXICAN TELEPHONE COMPANY.—The report of the Mexican Telephone Company, an American company with a nominal capital of $2,000,000, managed by a Board in the United States, shows the evils of working with too large a capital, which in the present case appears to have been due to an over-estimate of the business likely to be done by a telephone company in Mexico. The annual statement of the Company showed the number of telephone subscribers as follows :—In Mexico city, 538; Guadalajara, 125; Puebla, 50; Oaxaca, 44; Merida, 85. The Merida district (southern province of Yucatan) was the most prosperous, the receipts having increased from $3,598 to $5,190. The accounts of the Mexican office showed receipts $55,544, expenditure $53,370, and net earnings $2,174, making with the amount forward a balance on 1st March last of $2,295. The receipts of the Boston office were $1,299, but the expenses were $4,252. There was, therefore, a small deficit upon the whole undertaking.

THE SHEFFIELD TELEPHONE EXCHANGE AND ELECTRIC LIGHT COMPANY (LIMITED).—The first annual meeting of shareholders was held at the offices of the Company in Commercial-street on Thursday, May 16th, at noon. A satisfactory report was presented to the shareholders, of whom there was a good attendance, and a dividend of 7½ per cent., free of income tax, was declared, in addition to the sum of £793, which was carried to a reserve fund.

THE UNION ELECTRIC COMPANY OF AUSTRALIA (LIMITED) is being formed in Melbourne to purchase the businesses of the Electric Light and Power Supply Company of Australia (Limited) and the Southern Electric Company (Limited), Melbourne. Its capital is £1,000,000 in £1 shares. The Chairman of the new Company is Col. J. M. Templeton; Managing Director, Mr. T. T. Draper; Secretary, Mr. Charles Flesch, and the offices are situate at No. 66, Elizabeth-street, Melbourne. The new Company will have the exclusive agencies in Australia of the manufactures of Elwell Parker (Limited) and the Thomson-Houston Company.

UNITED TELEPHONE COMPANY.—Subject to audit the directors of this company have decided to recommend, at the general meeting to be held on May 29, a dividend for the half-year ending April 30 last at the rate of 12s. 6d. per fully-paid share, less income-tax, making, with the interim distribution, 17½ per cent. on the paid-up capital for the twelve months.

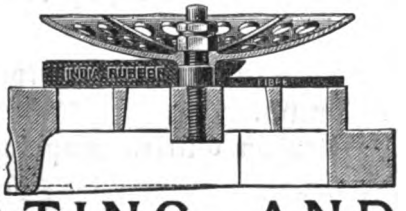
WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 17, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,544.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this Company for the half-month ended May 15, 1889, show an increase of £289 as compared with the corresponding period last year.

REMOVAL.—Messrs. Fairholme and Co., proprietors of the Cyclostyle Copying Apparatus, have removed to 34, Snow-hill, Holborn Viaduct, London, E.C.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Johnson & Phillips.
Nalder Brothers & Co.
Paterson & Cooper.
J. G. Statter & Co., Limited.

MANVILLE & MADGEN, *Managing Directors.*

3, Prince's Mansions, Victoria Street, Westminster.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 576.—Vol. XXIII. FRIDAY, MAY 31, 1889. Price Fourpence.

NOTES.

Although no one would venture to deny that where due precaution is not observed ships' compasses might easily suffer disturbance from the electric lighting appliances, yet it is happily true that the experience of ten years, extending over an enormous number of vessels, has not hitherto disclosed a single disaster arising from this cause. None the less should we be grateful to the President of the Institute of Electrical Engineers for directing attention to a question whose importance it would be difficult to over-estimate, especially since complete immunity from danger is easily attained, as Sir William Thomson was careful to point out. Whether or not it is necessary or desirable absolutely to prohibit the use of the single-wire system (with "ship-return") is perhaps a doubtful point in view of the remarkably good results which in the great majority of cases have attended its use. Mr. Alexander Siemens was able to state that in the whole course of his experience only two or three instances of the compass being affected by this method of wiring had come under his notice. We have reason to believe that this statement would be paralleled in the case of other firms. On the other hand it is impossible to dispute Sir William's contention that the single-wire system carries with it elements of danger in this respect, which are obviated by the employment of properly arranged double wires, or by the use of the alternate current. With regard to the latter method, it seems to us to be quite an open question whether, at least for large ships, the use of modern alternate current appliances (with or without a ship return for the secondaries) might not prove an economical as well as a perfectly practicable method of installation. Meanwhile the lesson to be learnt is that contractors should themselves ascertain, and, if desired, should certify, that the compass is free from disturbance caused by the electric lighting.

On Friday morning last, at the invitation of the Anglo-American Brush Corporation, a party consisting chiefly of the members of the Council of the Electrical Engineers (including the President) and the representatives of the technical press, assembled at the works in Belvedere-road to witness a repetition of the remarkable experiments on the Mordey Alternator, which were described in the Paper read by Mr. Mordey on the previous evening (see *The Electrician*, May 24th, p. 66). Of the experiments themselves we can add nothing to the lucid description given by Mr. Mordey except to say that each experiment was attended with perfect success, and as a demonstration of the entire practicability of alternate-current parallel working nothing further could possibly be desired. Since the above was written we learn that in a subsequent trial the full load of 50 h.-p. was put upon the machine during a continuous run, with the same success.

An ingenious and determined attempt to intercept the signals passing along the Marseilles cable of the Direct Spanish Company was recently discovered in the course of some repairs to the underground lines in the streets of Barcelona. The Superintendent found that at one spot the ground had been undermined and the four cables cut, the conductors on both sides being connected to insulated wires, which were taken to the wall of the house opposite. Outside this house the leads from each cable were connected together by a binding screw, so that communication between Marseilles and Barcelona was not interrupted. A careful inquiry was at once instituted by the authorities, and it was speedily discovered that the wires had been, at a period which can be traced, led into the cellar of the house opposite the mine, the hole in the wall having since been carefully bricked and plastered up. Fortunately the Direct Spanish Telegraph Company has, in consequence of certain occurrences which took place at an earlier period, adopted a system of working which makes it impossible to read the intercepted signals. As an instance of the ingenuity with which the attempt was made it may be mentioned that, instead of merely binding the wires forming the sheathing of the cables with small wire, clasps with screws to tighten them had been provided, which kept the outer wires in place after the cables had been cut through. The Spanish Government Telegraph Administration have taken the matter in hand, and every effort is being made by the authorities to secure the culprits. It is not necessary to go very far to seek the reason for this nefarious scheme. The Marseilles cable carries the important Bourse telegrams between Paris and Barcelona, and early information during the recent speculation fever was well worth the risk of detection. As it happened, however, owing to the precautions alluded to the design must have been entirely frustrated.

At the meeting of the Physical Society last Saturday Prof. Silvanus Thompson described a very pretty experiment, illustrating in a very direct manner the magnetic rotation of the plane of polarisation of a beam of light. The eye of a codfish properly mounted is traversed by a beam of polarised light, thrown, by means of a projecting lantern, upon a screen. A

Digitized by Google

clearly-defined black cross is then visible on a bright ground. If the beam of light is made to traverse a piece of heavy glass, or some other substance in which the magnetic rotation is considerable, then, as soon as the magnetising current is turned on, the cross is seen to rotate upon its axis with a rapid jerk through an angle depending on the thickness of the glass and the strength of the magnetic field. On breaking the magnetising circuit the cross jerks back to its former position with the same rapidity as before. The magnetic rotation was not exhibited at the meeting of the Society, but the black cross was projected upon a screen and caused to rotate through various angles by the interposition of plates of glass of different thicknesses. It forms a very pretty lecture experiment, and as the author pointed out, the proof of rotation is much more direct, and therefore more easily grasped, than the ordinary method of inferring it from the fact that in order to reproduce extinction after closing the magnetising circuit, or introducing a plate of quartz, as the case may be, one of the prisms has to be rotated through a certain angle.

In another column will be found the text of the circular in which the Directors of the United Telephone Company announce the terms which have been agreed to in respect of the amalgamation of the three leading Companies. It will be seen that the scheme is precisely in accordance with the arrangement which we foreshadowed in our issue of the 3rd inst. (p. 725). It is proposed that the United and the Lancashire and Cheshire Companies shall be absorbed by the National Company, the terms of transfer being £12. 10s. of new consolidated shares for each share of the United, £1. 6s. 3d. for the Lancashire, and £5 each for the National. We further understand that there is no ground for supposing that the Postmaster-General views the amalgamation with either dislike or apprehension; on the contrary, we believe the suggestion that the National Company should absorb the others came from Mr. Raikes himself. It further seems that he was precluded from sanctioning the transfer of the Licenses to a new company, as at first proposed, by the terms of the original concessions.

In our issue of May 10th we referred to the indignation which had been excited by the action of the Directors of the New Telephone Company in abandoning to their fate the purchasers of instruments which were supposed to be fully guaranteed. We now learn that this indignation has culminated in the formation of a strong combination, which, acting under legal advice, is about to commence legal proceedings to test the actual position.

The long outstanding question as to the true nature of diamagnetic action, over which Tyndall and Faraday long waged war, and agreed finally to differ, seems at length to be on the point of settlement. Mr. J. Parker, in the May number of the *Phil. Mag.*, followed by M. Duhem in the *Comptes Rendus* (20th March, 1889), have each attacked the question from the side of Thermodynamics. Mr. Parker shows that the phenomenon of diamagnetism, if interpreted in Tyndall's sense, *i.e.*, the existence of polarity opposite to that of paramagnetics, implies the contradiction of Carnot's principle, according to which we have been taught that it is impossible to obtain work by the transfer of heat from a cold body to a hotter. M. P. Duhem, after studying Mr. Parker's note, has been emboldened to go further, and by applying thermodynamic principles to the equations of magnetic induction he announces definitely that *the existence of diamagnetic bodies* [per se] *is incompatible with the principles of thermodynamics.* Becquerel's hypothesis (*i.e.*, that diamagnetism is merely the resultant of the magnetic forces acting upon the body and the medium in which it is suspended in the case when the permeability of the latter is the greater) would therefore seem to hold the field. In *The Electrician* of June 8th, 1888, we made some endeavour to analyse the question from the modern standpoint, and on purely physical grounds we arrived at the same conclusion.

The function of the condenser in an ordinary induction coil, although apparently a fairly simple matter, is in reality very little understood. We are inclined to believe that the explanation given by Dr. Fleming in another column contains the first complete and satisfactory analysis of the phenomena which actually occur.

The Students' *conversazione* at the Finsbury Technical College last week was very largely attended. Prof. Thompson talked pleasantly on "Arcs and Sparks" for about an hour and a-half, in which brief space of time he managed to sketch the history of the subject from the days of Otto von Guericke to those of Wimshurst and Macquaire, and to put the nerves of the non-technical members of his audience to a severe test by performing the apparently perilous feat of striking an arc in a bowl of paraffin oil. Those who were unable to digest the mild technicalities of Prof. Thompson's lecture could console themselves by listening to an excellent concert in the adjacent room. One of the most interesting features of the evening was the fine display of electrical apparatus. Amongst those exhibiting were Messrs. Woodhouse and Rawson, Messrs. Drake and Gorham, the Anglo-American Brush Corporation, the Acme Electric Company, and the General Electric Company. Messrs. Nalder Bros. and Co. showed a number of measuring instruments, including the latest type of secohmmeters. The Electric Apparatus Company exhibited some neatly finished electric bells with glass gongs, while one of Dr. Fleming's new standard resistance coils and some incandescent lamps for optical purposes were shown by the Edison-Swan Company. Messrs. Paterson and Cooper had an exhibit illustrating the construction of dynamo armatures, and the same firm also showed some large current ammeters. We must congratulate the students on a very successful and interesting entertainment.

We learn that some doubt is entertained by the Local Government Board as to whether the provisions of the Public Health Act, 1875, can be held to sanction the borrowing of money by local authorities for the purpose of undertaking the public supply of electricity. A case will shortly be submitted to the law officers of the Crown.

Digitized by Google

THE Technical Education Bill, introduced this session by Sir HENRY ROSCOE, and read a second time on the 8th inst., being shorn of some of the objectionable features of last year's proposals, has a fairly good chance of very shortly becoming law. The definitions of subjects included in the term "technical education" are certainly rather wide, including as they do commercial arithmetic, commercial geography, modern languages, and shorthand; but as the powers conferred, and above all the attendance, are voluntary, little objection can be taken to the principle of the Bill; and if worked with moderation and judgment it will probably not be burdensome to the ratepayers in practice.

THE following interesting paragraph appeared in a recent issue of the *Lancet*:—

At Bologna the other day the Communal library (a singularly rich collection) was visited by the Assessor, Signor Dall' Olio, who, in the course of his search, came on a *scaffale* (book-case) containing a vast number of volumes which had not been classified. They were at once put in hand for entry on the catalogue, and, among other highly important treasure-trove, was found a hitherto unknown treatise by Galvani on electricity. Some account of its contents is awaited with unusual interest.

The *Lancet* does not quote any authority for the statement, and up to the present we have been unable to find any mention of the matter in the columns of our esteemed contemporary *L'Elettricita*, of Milan. We shall hope, notwithstanding, that the discovery will turn out to be genuine.

WE are indebted to Dr. PULUJ for a description of some experiments which he has recently been engaged upon, and which have also formed the subject of a communication to the Academy of Vienna. Dr. PULUJ takes a metallic ball and hangs it by a bi-filar suspension centrally over the pole of a vertical magnet. The ball is then twisted round so that when let go it tends to spin on its axis by the untwisting of the suspension. Dr. PULUJ finds that in such a case the ball tends to rotate around the pole of the magnet in the same direction as that in which it spins on its own axis, and that the effect is independent of the direction of the polarity of the magnet. A mathematical investigation shows that this is the necessary result of the generation of Foucault currents in the rotating ball.

Trinidad-Demerara Cable.—We are officially informed that the cable between Trinidad and Demerara is interrupted.

Institution of Civil Engineers.—At the last meeting of the Institution of Civil Engineers Sir William Thomson was elected an honorary member.

Birthday Honours.—Amongst the recipients of birthday honours was Prof. Gabriel Stokes, M.P., President of the Royal Society, who was created a baronet.

New Post Office Cable Ship.—We understand the Post Office is about to invite tenders for the construction of a new telegraph cable ship for use in H.M. Postal and Telegraph Service.

Electric Lighting on the Midland Railway.—On Wednesday night the Midland Railway Company used the electric light for the first time on the London and Manchester and Liverpool express.

Gas and Electricity.—The Gas Company of Metz contemplates the establishment of a central lighting station, and the Gas Company of Venice has obtained the shareholders' permission for a similar object.

Ballymoney.—A meeting of the ratepayers was held last week at Ballymoney to consider the desirability of lighting the town by electricity. It was decided to bring the matter before the Town Commissioners.

The Westinghouse System.—The Paper upon the above subject which was announced to be read by Mr. J. S. Hambird on Tuesday evening before the Society of Arts was, at the last moment, unavoidably postponed.

A Man Killed by Lightning.—A man named Roger Alston, a gardener's labourer, was struck dead by lightning while weeding in a garden during a thunderstorm on Wednesday afternoon at Longridge, near Preston.

Shanghai.—The French quarter at Shanghai is to be lit by the electric light after April 1st, 1891. Tenders must reach Shanghai before the end of next December. M. A. Servaut, 6, Rue de Braque, Paris, will furnish all particulars to those interested in the matter.

The late M. Lucien Gaulard.—The Italian Society of Electricians has opened a subscription for the purpose of erecting a memorial of the late M. Lucien Gaulard. Subscriptions will be received in Paris up to the end of May by MM. E. L. Naze et Cie, 6, Rue Franche-Comté.

Coastguard Stations and Telegraph Offices.—On Friday last, in reply to a question by Sir G. Baden-Powell in the House of Commons, Lord G. Hamilton said there were round the coast of the United Kingdom and Ireland 750 coastguard stations, of which 325 were within one mile of a postal telegraph office.

Bath.—We are glad to learn that, notwithstanding the fact, recently announced in our City Notes, that the Bath Electric Light Company had failed to raise the required capital in the locality, yet that owing to Mr. Massingham's energy and perseverance there is no probability of the scheme being allowed to fall through.

Woking.—A company is about to be formed for the purpose of supplying Woking, which at present is not even lighted with gas, with the electric light. The capital of the new company is to be £20,000, and a provisional agreement has already been entered into with Messrs. Renshaw, King and Co., of Staffordshire, to supply the light and all accessories.

Douglas.—The tender of the Manchester Edison-Swan Company has been accepted for the lighting of Castle Mona Pavilion, Douglas, Isle of Man. The work is to be finished by the middle of July. The installation will consist of four dynamos, two supplying twenty 3,000 candle-power arc lamps, and two supplying 600 incandescent lamps of 16 candle-power each.

Electric Traction on the Metropolitan Railway.—The Unopposed Bill Committee of the House of Commons has passed the Omnibus Bill of the Metropolitan Railway Company, which, among other powers, authorises the company to work their line by engines "propelled by electricity, or any other mechanical power, either in addition to or in substitution of steam power."

Bournemouth.—A movement is on foot for establishing a Polytechnic at Bournemouth to provide technical instruction and promote the study of science and art in that locality. Mr. Wm. McGregor, M.I.E.E., who is well known as a retired officer of the Indian Telegraph Service, and who has taken the project in hand, appeals for pecuniary or other help from all friends of technical education.

Bristol.—The Electrical Committee of the Town Council met on Tuesday last and had an interview with Mr. Preece, who has on one or two occasions been called in to report to the Bristol Council as to their taking steps with regard to electric lighting, and has advised the postponement of action. It is thought that now the time has arrived when more practical action may be taken.

Personal.—We have to announce the marriage on the 15th May, at Malta, of Captain Robert Greey, of the Eastern Telegraph Company's cable ship "Amber," to Antoinette Clarisse, second

Digitized by Google

daughter of the Honorable Horatio J. Sprague, Esq., United States Consul at Gibraltar.—Mr. Melhuish, says the *Indian Engineer*, will succeed the late Mr. Johnston as electrician to the Government of India.

Electric Lighting in Surrey.—Mr. Stuart Rendell, M.P., is about to light Hatchlands, his country house, by electricity. The installation will consist of an 8 horse-power Marshall engine, Elwell-Parker dynamo, and 53 23L storage batteries of Drake and Gorham's latest type. The contract has been entrusted to Mr. A. A. Campbell Swinton. The installation will consist of about 150 16 candle-power incandescent lamps.

Frankfort-on-the-Maine Electro-Technical Institute.—The curriculum of the Frankfort Electro-Technical Institute for the term commencing this month has been issued. The major part of the lectures seem to be given by outside practical engineers, electricians, and manufacturers. There is also a special class on lightning conductors, a subject on which the minds of the German engineers, like our own, have of late been much exercised.

Exeter.—The Exeter Town Council has decided to grant permission to the Exeter Electric Light Company to erect 99 posts in positions to be approved by the City Surveyor for the necessary wires in a district covering the most important streets of the city. The permission was granted subject to a clause providing that, with the permission of the Council, the same posts might be used by any future applicant upon equitable terms.

Edison-Swan United Electric Light Company.—We are informed that the directors of this company have decided for the present to give up installation work, and that the company will devote itself entirely to the manufacture of lamps and first-class electrical fittings and instruments. Arrangements have been made with Messrs. Mather and Platt, of the Salford Iron Works, Manchester, to undertake the installation work which has heretofore been carried on by the Edison-Swan Company.

Bank Lighting.—Although there is so much central station work in progress we still find that the City banks are adopting the system of gas engines and accumulators which has been working so successfully for many years. Messrs. Drake and Gorham are now engaged in fitting up the Bank of Africa in Cannon-street, and we may mention that at the Union Bank of London, where there are over 300 lights, which have worked an average of 1,500 hours during the past year, there has never been a failure of the light, and we are informed that the working cost has come out considerably below the prices which are now quoted by the Supply Companies.

Temporary Lighting.—On Wednesday last Messrs. Woodhouse and Rawson (Limited) carried out a very successful example of this type of lighting at the Drapers' Hall (of the permanent lighting of which they have also the maintenance). The additional lights were placed in the courtyard, which was covered over with a canvas roof. In the centre, where the drapery was suspended from a centre ring, a large paper Japanese umbrella was hung, from the points of which were dropped 40 ten candle-power lamps, making a very effective electrolier. Below this was a large terra-cotta basin filled with beautiful exotics; the surrounding corridors were lit by suspended lamps in ornamental shades. Fifty-three 24L. E. P. S. cells were used with the usual satisfactory results.

Leeds.—At a meeting of the Electric Lighting Committee of the Leeds Corporation, held on Wednesday last, the borough engineer read a report relating to the work of the committee since 1883, when the Council granted a sum of money for electric lighting purposes. The report also contained a scheme for lighting the centre of the town by electricity. Mr. Hewson suggests that a central electric lighting station should be established on the piece of land known as the "Midden." At the outset he proposed that the plant, &c., should be provided to meet the requirements of that part of the town bounded by Leeds Bridge, North-street, Vicar-lane, and Park-row. The estimate of this would entail an expenditure of £61,000. Eventually provision could be made at the central station for the lighting of the whole of the borough by electricity. It was decided to print the report, and the committee adjourned its meeting till June 12th, in order that the members might have time to consider it.

The Visit of American Engineers.—The large party of Civil and Mechanical Engineers who are about to visit this country on their way to the Paris Exhibition, are expected to reach Liverpool on June 5th. After spending a week in visiting the great railway and industrial centres in Lancashire, Yorkshire, and the Midland Counties, they will arrive in London on the 12th June. On Thursday, the 13th, the whole of the gentlemen will be entertained by the members of the Institution of Civil Engineers at dinner, which will take place in the Guildhall of the City of London, by the express sanction of the Lord Mayor, Aldermen, and Common Council. During the following five or six days arrangements have been made for visits to various places of interest in London and the neighbourhood. Excursions up and down the River Thames will be organised, and various privileges will be granted in order to render the visit a memorable one. The Institution of Civil Engineers, with their well-known public spirit and hospitality, are actively exerting themselves in the matter.

Thunderstorms.—Severe thunderstorms occurred in various parts of the kingdom on Thursday last week. At Bradford there was a display of globular lightning; several houses were struck, and one was set on fire. At Walthamstow a porter was killed by lightning, and a woman was found dead in her house near Alfreton, having been struck by lightning. In Leicestershire three men took shelter in a hovel, which was struck, and one of them was killed. The old Abbey Gate House at Worksop was struck by lightning and greatly damaged. In Northamptonshire, Huntingdonshire, and Cambridgeshire much damage has been caused by thunderstorms. On Friday last the spire of Barrowden Church, near Stamford, was struck by lightning, and it is now in such an unsafe condition, about 20ft. being out of perpendicular, that it is considered dangerous to hold service in the church. In Huntingdonshire a fireball destroyed some farm buildings and stacks, and a number of horses and cattle in the district were killed by the lightning. From Germany it is reported that the powder magazine in the old fortress of Königstein has been struck by lightning and exploded, though without causing any loss of life.

Birmingham.—We understand, says the *Birmingham Daily Post*, that the negotiations between the General Purposes Committee of the Birmingham Corporation and Messrs. Chamberlain and Hookham have practically terminated, and that the issue of the Provisional Order promoted by the latter may be considered a certainty. The final form of the Order, as settled by the promoters in consultation with the Board of Trade and the Public Works Committee, limits the Order to a restricted area of the city, composed principally of Market Hall Ward. The promoters will be required to form a company with a capital of £50,000. There were till within the last few days some differences between the committee and the promoters with regard to a few of the details, but some of these have been arranged. On other points, including certain protective clauses usually required by the Corporation to be inserted in local Acts of Parliament, Messrs. Chamberlain and Hookham are willing to submit to the ordinary conditions. With regard to certain objections made to clauses in their own and in the London and other Provisional Orders, the promoters say that they will accept the general ruling of the Board of Trade. The promoters are prepared to proceed with the formation of a company the moment the confirmation of the Order takes place.

Stockport.—A meeting was held in Stockport on the 21st inst. to consider the proposal to form an electric lighting company in the town. Mr. J. S. Raworth, of the Anglo-American Brush Corporation, said if the proposed company put down a 5,000 or 6,000-light plant, electricity could be supplied at 3½d. per Board of Trade unit, and yield a return of 10 per cent.; with a less number of lights than this the price might be 4d. per unit. The capital of the company would be £10,000, but only about £8,500 would have to be spent at the start. Mr. J. J. Mann, the Manchester representative of the Anglo-American Brush Corporation, produced the plan of a suitable site for the central station in the Carrs, where 1,200 square yards of land was

Digitized by Google

available. The Brush Company would undertake to construct the works and supply plant for 2,000 16 candle-power lamps, and hand the place over to the Stockport Company in working order, taking one-third of the payment in shares in the local company. He had been promised that at least 2,000 lights would be taken up. After some further remarks from gentlemen interested in the scheme the meeting terminated, the general opinion being that a larger station would pay better. Although no committee was formally elected, it is understood that the matter will be pushed forward and a board of provisional directors appointed to register a limited company to prosecute the scheme.

Major Marindin's Report.—On Thursday, the 23rd inst., Sir G. Campbell asked the President of the Board of Trade whether Mr. Calcraft's letter of May 18 regarding electric lighting in the Metropolis correctly expressed the present intention of the Board of Trade to adopt Major Marindin's proposals to set aside the provisions of the Act of Parliament of 1888 requiring the previous consent of the local authority in many cases; whether the Board of Trade had approved the proposal of Major Marindin that the mere objection by a local authority should not be considered sufficient to exclude any company unless the local authority was itself ready at once to undertake the supply of electricity and gave evidence of its intention to do so. Sir M. Hicks-Beach said, in reply, that Mr. Calcraft's letter correctly expressed the present intention of the Board of Trade. Major Marindin's report, however, did not go so far as was suggested in the second paragraph of the question. If in any case the consent of a local authority was dispensed with, the special report of the Board of Trade would be laid at the earliest possible moment before Parliament. It would not be consistent with the provisions of the Act of 1888 to insert in any Provisional Order any clause injuring or restricting the subsequent granting of a License or Provisional Order to the local authority or any other person within the same area.

The London County Council.—At the meeting of the London County Council last week the Highways Committee reported that they had had before them a notice by Messrs. Latimer Clark, Muirhead and Co., that, in pursuance of powers conferred on the St. James's and Pall Mall Electric Light Company, under License granted by the Board of Trade, they proposed to lay electric light mains and distributing boxes under certain thoroughfares in the parish of St. James, Westminster. The Vestry of St. James's had already consented to the laying of the mains referred to in the notice, and the Committee recommended that the consent of the Council be likewise given, on condition that the work should be carried out to the satisfaction of the proper authorities.—Mr. Haggis moved that the recommendation be approved. To this an amendment was proposed that the matter be referred back to the committee, it being urged that if the Council had the power they should only give their consent on conditions similar to those laid down by Major Marindin in his report on electric lighting in London. Mr. Haggis said the committee, of which he was the chairman, had before them the whole question of the electric lighting of the Metropolis. The recommendation in their report was, however, with reference to a company who had already had a License granted to them by the Board of Trade, and therefore that company had the right to lay the mains and boxes of which they had given notice to the Council. The amendment was agreed to.

Barnet.—At the last meeting of the Barnet Local Board a letter from Messrs. Ingledew, Ince and Co., solicitors to Mr. Joel, was read. The communication stated that while Mr. Joel desired to meet the Board in every reasonable respect, he reserved all his rights under his contract. The contract provided that he should apply for and obtain a License from the Board of Trade, and that the Local Board should assist him in doing so. The non-compliance of the Board with this provision would prevent Mr. Joel from putting the wires underground within twelve months, as required by Clause 5, and the Board must therefore release him from the obligation. Upon Mr. Joel's obtaining the license it would give him an interest extending over seven years in lieu of the three years provided by the Board, which would satisfy him for the large expense to which he had been put. Messrs. Ingledew also pointed out that the terms of the resolution passed on the 25th of April last (*The Electrician*, May 10th, p. 4) had been very prejudicial to Mr. Joel in his endeavour to make the lighting a success, and appeared to have been unjustified by the facts. Had the Board desired to defer for a time their consent to the application for a License, it might have been done without casting a stigma upon Mr. Joel, who now asked that the resolution should be rescinded. The Chairman (Mr. C. Stevens) said Messrs. Ingledew had just hit the point. The Board did not assist Mr. Joel to obtain a License for the very reason that it would give him seven years' tenure instead of three. Mr. James proposed that, as legal points were raised, they should, in the absence of their Clerk, refer the matter to the Lighting Committee, in conjunction with the Clerk. This was agreed to unanimously.

Conversazione of the Institution of Electrical Engineers.—The "conversazione" of the Institution of Electrical Engineers on Friday last was very largely attended, the guests of the President and Lady Thomson numbering some 735. Nearly all the leading Members of the Institution were present, and among the visitors were:—Sir Arthur Blackwood, K.C.B.; Sir James Crichton Browne, LL.D., F.R.S.S. (L. and E.); Sir Henry Doulton; Sir Thomas Sanderson; Sir John Coode, K.C.M.G.; Sir Juland Danvers, K.C.S.I.; General Eccles; Admiral Fitzroy; C.B.; Captain Creak, R.N.; Captain E. M. Shaw, C.B.; Col. Sir James Grant, C.B., F.R.S.; Captain Fisher, R.N.; Major Marindin, R.E.; Captain Boyle, Dr. G. C. Wallich; Prof. Frankland, F.R.S.; Dr. John Rae, D.C.L., F.R.S.; Dr. Gordon Hardie; Prof. Hering; Prof. H. Robinson; Dr. William Pole, F.R.S.S. (L. and E.); Dr. J. H. Gilbert, F.R.S.; Dr. W. H. Perkin, F.R.S.; Prof. W. H. Hudson, M.A.; Prof. H. E. Armstrong, F.R.S.; Dr. W. J. Russell, F.R.S.; Prof. James Groves, F.C.C.; Dr. Hugo Müller, F.R.S.; Prof. Hulme, F.R.S.; Prof. Meldola, F.R.S.; Prof. G. J. Romanes, LL.D., F.R.S.; Prof. Govier Seeley, F.R.S.; Prof. John Milne, F.R.S.; Prof. Hales, M.A.; Prof. G. T. Bonny, F.R.S.; Prof. W. Ramsay, F.R.S.; Dr. Bell, F.R.S.; Mr. J. G. Symons, F.R.S.; Sir Lowthian Bell, Bart., F.R.S.; Lord Sudely, F.R.S.; the Earl of Crawford and Balcarres, F.R.S.; Mr. Charles Cochrane, M.Inst.M.E.; Mr. William Anderson, M.Inst.C.E.; Prof. W. N. Shaw, M.A.; Mr. Ludwig Mond, F.C.S.; Mr. R. Brudenell Carter, F.R.C.S.; Mr. George Berkeley, M.Inst.C.E.; Mr. T. H. Blakesley, M.A.; Mr. Jacob Brett; Mr. H. J. Chaney; Mr. Charles Hawkesley; Prof. Huntingdon.

Halifax-Bermuda Cable.—In the House of Commons on Tuesday last Dr. Cameron asked the Secretary to the Treasury whether his attention had been called to the prospectus of the Halifax and Bermudas Cable Company, inviting subscriptions for £120,000 debentures, and setting forth "that the company has been incorporated for the purpose of carrying out a contract with Her Majesty's Government for laying a telegraphic cable between Halifax and Bermudas;" whether the sanction of the Treasury, as required by Article 11 of the Halifax and Bermudas cable contract, had been given to the transfer of the benefits of the contract from the International Cable Company to the new company; whether, as provided in Clause 14 of that contract, the International Cable Company, within seven days of the approval of the contract by the House, proved to the satisfaction of the Treasury that the £100,000 required "had been subscribed and fully paid up;" if not, whether under Clause 19 the contract had not "absolutely ceased and determined." In reply, Mr. Jackson stated that—(1) A conditional sanction to the transfer had been given; (2) the Treasury had modified Clause 14 in respect of the period within which it is to be proved that the capital has been subscribed and paid up, and had informed the company that they will accept such proof within one month from the date of the approval of the contract by the House of Commons. Under these circumstances the contract remained operative, one of its terms having been varied by agreement between the parties to it. In reply to further remarks by Dr. Cameron, Mr. Jackson said that if the contract varied in any essential point—as to the amount of the subsidy or the term of years it had to run—that would be contrary to the sanction given by the House, but he believed it was clearly understood that the Treasury had the power to vary the agreement.

THE FUNCTION OF THE CONDENSER IN AN INDUCTION COIL.

BY DR. J. A. FLEMING, M.A.

Fizeau appears to have been the first* to suggest that the action of an induction coil employed for raising the electromotive force of a current would be increased by the employment of a condenser. The mode of use is as follows :—Let P be a primary circuit which takes current from a few cells of a battery, and let I be an interrupter in the primary circuit, either automatically worked by the magnetisation and demagnetisation of the iron core or by any other means. Let S be a secondary circuit of many more turns and high resistance. Under these circumstances each break of the primary current is accompanied by the production of an electromotive force in the secondary capable of producing a discharge across an air space in the secondary circuit. This electromotive force in the secondary is increased by any action tending to increase the suddenness of the stoppage of the primary current, and decreased by anything promoting a spark at the points of rupture of the primary circuit. Fizeau found that if a condenser, formed of alternate sheets of tinfoil and mica or paraffined paper in such fashion as to form a Leyden jar, has its two opposite coatings connected with the two extremities between which the rupture of the primary circuit takes place, then the electromotive force in the secondary circuit under the same circumstances is increased. In most current text-books and elsewhere this action is explained by saying that the extra current in the primary circuit, instead of being expended in making a spark at the contact points, darts into the condenser and hastens the decay of the primary current. This explanation as generally given is, however, very imperfect. A more complete examination of the nature of the condenser action has been given by Lord Rayleigh (*Phil. Mag.*, Vol. XXXIX., 1870, p. 428, *et seq.*). In the experiments there detailed a sewing needle was submitted to the magnetising action of an induced secondary current produced by the "break" of current in a primary circuit. In some previous experiments by the same writer (*Phil. Mag.*, July, 1869, p. 9) it had been shown that the magnetising effect of the secondary current was *cet par* proportional to the *initial* strength of the induced current, and that this initial strength was proportional to the quotient of M by N, or to the value of the ratio of the coefficient of mutual induction to the coefficient of self-induction of the secondary circuit. It was then found that the magnetising effect of the secondary current was greatly increased by connecting the plates of a condenser respectively to the two points between which the break of the primary circuit occurred. The complete investigation of the values of the induced and primary currents would under these conditions be a good deal more complicated than the investigation of the more simple case of discharge of a condenser through a single inductive circuit. We are here, however, only concerned with the first part of the electrical motion, the manner in which the currents wear down under the action of the resistances being of subordinate importance. It appears that when the electrical motion is decidedly of the oscillatory type the first few oscillations will take place almost uninfluenced by resistance, and on this supposition the calculation (following Lord Rayleigh) becomes remarkably simple.

Let L, M and N be the primary, mutual and secondary inductance, and let i and i' be the primary and secondary current strengths at any instant, and q and q' the quantities of electricity which have flowed through these circuits from the instant of beginning to reckon the time t,

then $$\frac{dq}{dt} = i \text{ and } \frac{dq'}{dt} = i';$$

and if we neglect resistance effects, as we can do at the instant after "breaking" the primary circuit, and call C the capacity of the condenser bridging across the "break" of the primary circuit, the equations giving the values of the primary and secondary current i and i' at the instant after breaking the primary circuit are—

$$L\frac{di}{dt} + M\frac{di'}{dt} + \frac{q}{C} = 0 \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$M\frac{di}{dt} + N\frac{di'}{dt} = 0 \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Eliminating i' we have

$$\left(L - \frac{M^2}{N}\right)\frac{di}{dt} + \frac{q}{C} = 0 \quad . \quad . \quad . \quad . \quad . \quad (3)$$

(3) may be written

$$\left(L - \frac{M^2}{N}\right)\frac{d^2q}{dt^2} + \frac{q}{C} = 0 \quad . \quad . \quad . \quad . \quad . \quad (4)$$

A differential equation of this type always indicates an oscillatory motion. For consider the simple periodic function, $x = A \sin nt$, where $n = \frac{2\pi}{T}$, T being the periodic time of the motion, we have $\frac{dx}{dt} = nA\cos pt$, and $\frac{d^2x}{dt^2} = -n^2 A \sin pt$; hence, $\frac{d^2x}{dt^2} + n^2 x = 0$, and therefore $x = A \sin pt$ is a particular solution of this equation.

In the above differential equation n is seen to be 2π times the frequency of the oscillation.

Accordingly, equation (4) indicates an oscillation of the primary current, of which the periodic time is equal to

$$2\pi\sqrt{C\left(L - \frac{M^2}{N}\right)},$$

and this is the periodicity of the electric oscillation set up in the primary at the first instant after "break."

Equation (2) gives by integration the connection between i and i', and it is

$$Mi + Ni' = \text{constant} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

which shows that the currents in the primary and secondary oscillate synchronously, the maximum of the one coinciding with the minimum of the other. Since i' is zero at the instant of "break," the constant in equation (5) must be equal to M I, where I is the current strength in the primary just before "breaking" primary circuit.

Accordingly, we have

$$i' = \frac{M}{N}(I - i),$$

so that when, after half an oscillation of the primary, i becomes equal to $-I$, we have

$$i' = 2\frac{M}{N}I \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

This equation gives us the *initial* value of the secondary current i' in terms of the value of the primary current just before the "break" when the condenser is used. It is easy to show (*see* Chrystal's article "Electricity," *Encyclopædia Britannica*, IX. Ed., p. 81) that, if the condenser is not used across the "break" of the primary, the initial value of the secondary current under the assumption of a perfectly sudden break is equal to $\frac{M}{N}I$; hence we see that the value of the secondary current, just immediately after the break of the primary, is *double* that which is there deduced as the value when the primary is simply suddenly stopped without the intervention of the condenser. Stripped of symbolism, what the above amounts to is this: if a condenser is inserted across the "break points" of a primary circuit, then on breaking the primary current continues to run on into the condenser for a little bit; it then *rebounds*, and is reversed in sign, retaining initially its full strength. The electromotive force set up in the secondary circuit is then the result of a stoppage of a primary current and its *immediate reversal* in direction, and this is equivalent to the removal of a certain number of lines of induction from the secondary circuit, and their immediate insertion into it in the opposite direction. Hence, when a condenser is so employed the inductive electromotive force in the secondary must be just double that which it would be if there were no such rebound of the primary. The con-

* *Comptes Rendus*, Vol. XXXVI., p. 418, 1853.

Digitized by Google

denser acts by setting up electrical oscillations, and it does away with the spark, or largely diminishes it, in virtue of the fact that the condenser acts at the moment of "break" as if it were a shunt circuit of negative self-induction, only with this difference—that instead of dissipating energy like a conducting circuit it returns it again to the primary circuit in the form of a reversed current, and increases the total change of induction through the secondary circuit in the short interval of time immediately succeeding the "break."

Since the sparking distance of the secondary current depends on the initial electromotive force in the secondary—that is, on the maximum of the electromotive force—we see that the condenser so applied can greatly increase the sparking distance of the secondary discharge.

The action is essentially a phenomena of *resonance*. The condenser causes an elastic recoil in the current and enables the electro-kinetic energy of the steady primary current to be utilised in producing secondary electromotive force rather than suffer dissipation in the form of a contact spark. In order to be efficient in quenching spark the capacity of the condenser must be great enough to take up the full primary current, or to receive charge at a rate equal to the delivery of the full primary current for a time during which the contact or break points are separating to a distance too great to permit of much sparking jumping across. There is a certain capacity of condenser suitable for any given coil which produces the most beneficial result in quenching contact spark and lengthening secondary spark. The required capacity is best determined by trial, since the experimental data necessary to furnish the means to calculate it would be probably more difficult to obtain, owing to the fact that it will be determined by several variables, viz., the effective resistance and inductance of the primary circuit, the rate of breaking, and probably also by the amplitude of movement of the "break points." If the primary coil of an induction coil is traversed by an alternating current then the condenser as ordinarily used becomes superfluous. It will be remembered that the late Mr. Spottiswoode obtained secondary sparks of great magnitude from his large coil by so using the alternating current of a de Meritens machine.

REVIEWS.

The Telephone. By W. H. Preece, F.R.S., and J. Maier, Ph.D. (London: Whittaker and Co., 1889.)

The lack of a comprehensive treatise on the Telephone has long been apparent. In every other important branch of electro-technics we have writings—good, bad, and indifferent—enough and to spare, but with the exception of the usual "popular" handbooks, and one or two historical memoirs, surprisingly little has hitherto been written on the Telephone. Under these circumstances, the authors would be deserving of some gratitude had they given us an only moderately satisfactory treatise, but as a matter of fact there can be no hesitation in awarding to the volume before us higher praise than this. If not absolutely incapable of improvement, still we are honestly of opinion that this volume adequately fulfils its authors' intention, and will long remain the standard work upon the subject with which it deals.

In view of the fact to which allusion has just been made, that it is practically the first work of the kind, we shall proceed to give a somewhat full synopsis of the contents.

The first two chapters deal with the elementary theories of Sound and Speech and of Electro-magnetic Induction. The authors have succeeded in saying all that needs to be said (for the purpose in view) within less than 20 pages. We have then two chapters devoted to the discovery of the Bell Telephone and to the electrical properties of carbon under pressure. The credit of priority as regards the latter discovery is assigned to Edison, but stress is laid upon the fact that in practice Edison's "button of compressed carbon" has long since disappeared, every telephone transmitter in use to-day being essentially a Hughes Microphone. This is a fact with which electricians are perfectly familiar, but we could wish that it were better known to the general public. We have next a chapter on Theory, in which the famous experiments of Shelford Bidwell and of Stroh are recounted; but it is admitted that no complete and satisfactory theory either of transmitter or receiver has yet been advanced. Next we have three chapters devoted to the description of instruments. It is well known that since 1876 the Governments of the civilised world have derived no inconsiderable portion of their revenues from the granting of patent rights for the "invention" of various patterns of Bell receivers and carbon transmitters, and it will be conceded that in limiting their detailed description to only nine varieties of receivers and twenty-one transmitters the authors exhibit a commendable moderation. There is, in addition, an interesting chapter on "Special Telephones," describing some of those instruments which are not, properly speaking, either Bell receivers or carbon transmitters. Here we find the Edison "Electro-Motograph," Breguet's Mercury Telephone, the Photophone, the Radiophone, Preece's Thermo-Telephone, and Forbes's Thermal Transmitter. No mention is made of the interesting electrostatic receiver of Dolbear, or of the recent "water-jet" transmitterof Chichester Bell.*

The next chapter deals with "The Comparative Efficiency of some Transmitters." The authors observe, with much reason, that "Transmitters as well as receivers present the peculiarity that it is difficult to compare them with one another in the same exact manner that we compare, for instance, the electromotive forces of two batteries or the output of two dynamos." The authors think, however, that the importance of properly designing the induction coil has been too much overlooked. In some experiments carried out by the British Post Office, which have also been confirmed by the results arrived at by the Swiss Administration, it was found that the best effect was obtained with a coil constructed as follows:—Primary circuit, 180 to 185 windings of wire of ·6 millimetres (No. 23 B.W.G.) and ·5 ohm resistance; secondary circuit, 4,100—4,300 windings of wire ·15 millimetres diameter (No. 28 B.W.G.) and 250 ohms resistance. These experiments were made with a Blake Transmitter, and it does not follow that the same result would be attained with a transmitter, say, of the Hunnings type, where a much larger current passes in the primary.

The chapter on Telephone Wire is divided into two sections—(A) air lines, and (B) cables. It contains, amongst other things, an elementary discussion of the behaviour of iron and copper wires towards Telephonic currents, the various causes of disturbance on Telephone circuits, the methods of running "twisted" wires, the tests for copper wire employed by the British Post Office, and a Table of sags and stresses (on which subject there was an interesting and animated discussion in this journal about a year ago). One of the large iron frames used by the United Telephone Company on the London house-tops is shown in a full-page engraving, but we are a little surprised that the authors have nothing to say against the practice followed by this Company of employing double shackles where upright insulators would be both less costly and more efficient. Earth connections are mentioned here, but are condemned as "essentially bad" twenty-six pages later. The authors make no mention of the plan adopted at Richmond, Va., and some other places in the States (and very possibly elsewhere), where a common return wire is run upon many of the pole lines to which all circuits are joined up. This arrangement is not much more costly than the earth return, and it is said to have given excellent results in practice so long as care is taken to keep the return wire well insulated from earth. It is obvious, however, that it does not afford anything like as complete a cure for induction troubles as that given by a metallic loop.

Coming to the question of cables, reference is made to the practice introduced by Mr. Preece in 1878 of covering each wire separately with a coating of lead or tin-foil to act as an inductive shield; and it is pointed out that in order to be thoroughly effective the coatings must not only be very heavy, but must also be connected together and to earth. The authors state that "the efficiency of the lead covering is not due to the fact that it acts as a shield between one wire and another, but that

* See *The Electrician*, July 27, 1888, p. 375

Digitized by Google

it forms a return circuit for the currents surrounding the prime wire." It is a little difficult to ascertain the exact meaning of this statement, since in general if there were no metallic shield there could be no such currents; but if the authors intend to deny the existence of the action termed "shielding," they are certainly in the wrong. By the aid of the formulæ developed by Dr. Fleming in *The Electrician* of January 11th and 18th, 1889, it would be easy in any given case to ascertain the necessary conditions for effective shielding, and hence to determine up to what point, if any, the game is worth the candle. The remainder of the chapter is devoted to underground cables, the methods of construction adopted by the chief makers being described in detail. The authors insist that lead-covered cables should never be buried in the soil without external protection.

Passing over a chapter on Auxiliary Apparatus—call-bells, lightning-protectors, &c.—and two chapters on the circuit connections of individual lines, we come to the most important section of the book, consisting of eight chapters on Telephone Exchanges. Here we may reasonably find some fault with the arrangement of the matter. Without any preliminary remarks upon the nature of an exchange service, we are plunged at once into a detailed description of the system adopted by the British Post Office, and it is not until we come to the following chapter on the German system that we are told that "all Telephone Exchanges are based upon one or other of two leading principles." These two principles are briefly—(1) The operator at the Exchange calls up the subscriber who has been asked for and informs him of the fact; (2) The first subscriber is merely "put through" upon the line asked for, and left to his own devices. The first system is obviously the more onerous for the Company, and requires a larger staff to work it properly; but this disadvantage is partially counterbalanced by the fact that it does not require a special ring-off signal, which is a great source of complexity in most systems of the second class. The authors have not attempted any more detailed classification; but we think it would not be altogether impossible to present the leading features of the chief systems in a schematic form, which would greatly facilitate their comparison. From a more purely technical point of view it would seem better to divide the systems broadly into "multiple" and non-multiple or simplex exchanges.

Amongst the latter class the system of the British Post Office, though not the cheapest, is probably unsurpassed in the efficiency of the service rendered. Space will not permit us to recount all the ingenious devices which render the working of this system as nearly perfection as any non-multiple system can become, but we may briefly indicate some of its chief peculiarities. Each subscriber is provided with a battery of two or three Daniell cells, *by which a constant current is maintained upon the line.* To communicate with the Exchange he merely lifts the telephone from its hook and finds himself at once *en rapport* with the operator. The operator receiving the number wanted calls the second subscriber. This is effected by means of a powerful battery, which actuates a relay connected with a local bell circuit at the subscribers' end. The relay is unable to respond to the weaker "permanent" current. At the close of the conversation the subscribers merely hang up their telephones, and the restoration of the permanent current gives a clearing-out signal in a quite unmistakable form. Metallic circuits are alone employed, and underground wires are used as far as possible.

Besides the advantage gained by the simplification of the subscribers' duties this system possesses several subsidiary advantages, such as the immediate detection of a fault on the line by the failure of the permanent current, convenience of daily testing, &c., but like every other non-multiple system it is ill adapted to the wants of a large exchange. Not more than fifty subscribers can be attended to by each operator; for any larger number the operators requiring cross-connections have to instruct each other by word of mouth, a condition which speedily imposes its own limit.

Passing on from the Post Office system, we naturally expect in a work of English origin to find some account of the much more extensive systems of the National, the Lancashire and Cheshire, and the United Telephone Companies. But this is not the authors' plan. We are taken all over Europe, and we visit America before we get back to our own country; and even then no systematic account of the development of the English Telephone Companies is anywhere attempted. The authors have little or nothing to say about the extension of inter-urban telephony in these islands, and indeed an ignoramus would probably gather from this book the idea that the telephone was in the hands of the Post Office to a very much larger extent than is really the case.

We next find a chapter on the German system, which is also non-multiple, and belongs to the authors' 2nd Class. Its most distinctive feature consists in the very excellent call and ring-off system. In practice the arrangement works as follows:—The subscriber first presses the call-button to ring up the exchange; this sends a positive current. He then unhooks the telephone and asks for the line wanted; on hearing that he is through he again presses the same button, but the telephone being now off the hook, the result is to send a *negative* current. This has no effect upon the polarised indicator at the Exchange, but it rings the subscriber's call-bell. When the conversation is finished the act of re-hanging the telephone *automatically* sends a positive current to line, which acts as a ring-off signal.

The French system, which is described in the next chapter, though still non-multiple, is somewhat more distinctive in character. Like the English Post Office system the speaking circuits are metallic throughout, but an earth connection is also made use of in order to obtain the advantage of a "direct call" between subscribers, similar in practice to that which has just been described. Two keys are provided, one of which rings up the exchange on the metallic circuit, while the other calls the subscriber (when the lines are "through") on the earth circuit. This arrangement offers great facilities for clearing-out signals, but it is a rather serious drawback that every subscriber has to be provided with no less than nine Leclanché cells.

The Paris Exchange numbers about 6,000 subscribers, distributed between twelve local exchanges, which are connected by 424 trunk lines. The details of the exchange connections are fully described.

The Swiss system is next described. It is also a non-multiple system, belonging to the authors' 1st Class, in which the subscriber wanted is called by the exchange operator. The tariff is probably the lowest in existence, being only £6 per annum. The public call-office system is well developed in this country, but non-subscribers are not allowed to speak over the trunk wires, with which most of the principal towns are now connected together.

So far we have been dealing with the methods employed by the official administrations of the European countries, but in the next chapter various non-multiple exchange systems are mentioned, most of which have found only a limited application. The "Law" system, which is first described, is in use in New York and in Brooklyn, and under a greatly improved form also in the Dundee district of the National Telephone Company. The distinctive feature of this system is the use of an independent calling circuit common to a large number of subscribers. The subscriber first switches his telephone into the call-wire circuit, and immediately gives his own number and that of the subscriber wanted. The operator, who is always listening, takes the peg attached to a flexible cord belonging to the number required and presses it against a plate connected with a battery, thus ringing that subscriber's bell; he then inserts the two pegs into a common bar, and the two subscribers are in communication as soon as the first subscriber has switched his telephone out of the call circuit. It will be seen that no indicator is required in this system, but on the other hand the operator has to receive the clearing-out signal by word of mouth, which may or may not be given by the subscriber. The great disadvantage of the system as originally designed lies, however, in the fact that the long looped call wire forming only one circuit was extremely liable to interruption. Mr. Mann, the engineer of the National Telephone Company's Dundee District, has effectually overcome this difficulty by making the connections of the wire in what an electric light engineer might describe as irregular series-parallel, so that omitting the earth connections, a diagram of the circuit looks like the trunk and branches of a

Digitized by Google

tree. Mr. Mann has introduced other improvements in detail, and the working of the Dundee exchange leaves nothing to be desired—it is, in fact, one of the most satisfactory in the whole system of the National Company.

The Gilliland switch-board is still extensively used in America, although its design dates back to very early days. The lines are brought to a series of perpendicular bars or strips, and connection is made with other lines, or with the calling battery, by plugging in any one of a series of horizontal bars crossing at right angles. The details have been somewhat improved of late, but loose plug-boards are obviously doomed to disappear. The Williams spring switch-board is so far an improvement that connection is made by plugs attached to flexible cords, and consequently only one plug-hole is required for each subscriber. In working it closely resembles the method adopted by the Swiss Government. Messrs. Naylor Bros., of Berlin, have designed an ingenious though somewhat complex system; and lastly, there is the Chinnock system, which is used in five of the New York exchanges, and is much like the Gilliland in its general design, but instead of having the two sets of bars in one plane the horizontal bars lie underneath, thus making the arrangement much more compact.

The future of telephony in all large exchanges now admittedly rests with the "Multiple Switchboard." The authors do not mention—in fact, it is not generally known—that this principle was worked out in England by the engineers of the United Telephone Company well nigh simultaneously with its introduction in America by the Western Electric Company. At the date of the English patent of the American invention a multiple board was actually in process of construction at the Chancery-lane exchange, but no publication having been made the patent was unassailable. The principle of the multiple board is very simple; it consists in giving to each operator (as usual) only a limited number of subscribers to attend, but at the same time in placing within his immediate reach the means of coupling these subscribers' lines to any other line which enters the exchange; in fact, every subscriber's line after being taken to an annunciator at one section is carried on from section to section throughout the board, and in every section it is brought to a plughole whereby connections may be made in the usual way. This system, of course, involves an enormous multiplication of wires within the exchange, and much ingenuity has been expended in planning out clear and systematic methods of dealing with the wiring and making proper provision for testing the circuits and varying the connections.

One of the latest and most successful exchanges on this system in our own country is that of the National Telephone Company at Manchester, where several novel and highly valuable features have been introduced. This switchboard is built for no less than 4,200 subscribers, although only 1,600 are at present connected. The improvements introduced at Manchester have chiefly to do with the methods devised for readily testing or altering the connections of any given circuit, and in these important points the arrangements adopted would seem to approach perfection. At the same time the actual quantity of wire required for the connections has been considerably reduced. The extensive trunk wire system which radiates from Manchester has been dealt with—so far as the exchange service is concerned—in an ingenious and effective manner, but our space will not permit us to go into detail.

The question of "Intercommunication between two distant Telephonic Networks" occupies the next chapter. The problem to be solved is usually that of connecting two single wire (earth return) circuits at each end with the intermediate metallic circuit of the trunk line. This is effected by means of induction coils or translators. One of the earliest and most effective systems is that of Mr. Bennet. Slightly different arrangements have been devised by Nyström and Elsasser. The succeeding chapters deal with Public Telephone Stations, Automatic Connection Registers, and Multiplex and Long-Distance Telephony. Multiplex Telephony is at present of little value. It simply means using a double wire (1) as a complete metallic circuit, and (2) simultaneously as an earth circuit, with the two wires in parallel. (See *The Electrician*, November 12, 1886, p. 18). After describing the Van Ryssel-berghe system of Simultaneous Telegraphy and Telephony, the authors refer to some of the long-distance experiments which have been carried out in America, and they sum up the results as follows:—

"Telephonic communication, satisfactory even from a commercial point of view, has been carried on:

With a [copper] wire of 2·1 mm. [dia.] at a distance of				500	kilometres.
"	"	2·7	"	941	"
"	"	6·0	"	1,625	"

These experiments seem to show that the question of long-distance telephoning has nothing whatever to do with the kind of telephone used, the condition of the conductor alone being the decisive factor."

One or two chapters are devoted to a description of the various devices, most of them equally ingenious and intricate, which have been suggested with a view to the connection of several subscribers on one circuit. Of these, one of the best, and certainly the best known in this country, is that of Mr. Sinclair, of Glasgow. A chapter on "The Telephone Applied to the Telegraph Service," and one on "The Telephone as a Military Instrument," brings this valuable work to a close.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"On the Security against Disturbance of Ships' Compasses by Electric Lighting Appliances."*

BY SIR WILLIAM THOMSON.

The danger to be avoided is sufficiently explained in the following short statement by Mr. William Bottomley, which appeared in the *Nautical Magazine* for December, 1885:—

"The following example of a case, which might occur in any large ship, will show the amount of error which may be produced on the compass" [by the electric lighting apparatus] "unless precautions are taken to guard against it.

"Suppose a main lead from the engine room to the fore part of the ship, to light up 100 lamps, is brought along the centre of the ship. It may be at a distance of 10 metres, or 33ft. from the standard compass, and will run almost underneath it. If we suppose that each lamp takes one ampere of current there will be a current of 100 amperes altogether in this lead. Now, the effect" [of an infinitely long straight current] "on the compass" [above it] "at a distance D in centimetres is given by the formula

$$F=\frac{2\times\frac{1}{10}C}{HD},$$

where C is the current in amperes and H is the horizontal magnetic force. In this case we have C=100 amperes and D=1,000 centimetres. Therefore,

$$F=\frac{20}{1{,}000\,H}=\frac{0{\cdot}02}{H}.$$

At Glasgow the horizontal force may be taken as 0·15 in C.-G.-S. units, therefore the effect on the compass will be $\frac{0{\cdot}02}{0{\cdot}15}=\frac{1}{7{\cdot}5}$. This will be expressed in degrees by multiplying by 57·3, the number of degrees in the radian, or angle subtended at the centre of a circle by an arc equal in length to the radius. Therefore, the amount of error produced by such a current on the compass will be $\frac{57{\cdot}3}{7{\cdot}5}=7{\cdot}6$ degrees.

"The foregoing refers to a single wire and a continuous current machine, but if an alternate-current machine is employed no effect will be produced on the compass even when the ship's side is used for the return. When a continuous-current machine is used, the danger of producing an error on the compass can be avoided by using two wires close to one another, but these wires should be well insulated from the ship's side. If in any way" [two points of] "one of the wires is brought in contact with the iron of the ship there may be no change observable in the lighting, but the current may produce as much error on the compass as it would if there was only a single wire.

"The following points should therefore be attended to in all case of lighting ships by electricity:—

"First.—With continuous current machines two wires, well insulated, should always be employed.

"Second.—The insulation of the wires should be tested periodically; if any connection with the iron of the ship is found the fault should at once be made right.

"Third.—When an alternate-current machine is used, a single

* Read before the Institution of Electrical Engineers.

Digitized by Google

wire may be employed and the iron of the ship used to complete the current without producing any effect on the compass.

"What makes this question of the greatest importance is that the error may be produced without ever being detected by the officers of the ship. On board ship the errors of the compass are usually determined during the day, in the morning and afternoon, but the electric light is only used at night. The captain may therefore carefully determine his errors every day, and set his course quite correctly; but at night, when the electric light is turned on, the ship may be going several degrees off her proper course, although she is being correctly steered by the compass.

"In connection with the lighting of ships with electricity there is another point which should also be attended to—that is, the position of the dynamo. If it is placed near an iron bulkhead, the upper end of which is near the compass, the bulkhead may become magnetised by induction so powerfully that it will produce a considerable error on the compass."

The subject was also referred to in Mr. Bottomley's Paper on "The Magnetism of Ships and the Mariner's Compass," read before the Society of Arts, January 28th, 1886, and published in the *Journal* of the Society for February 5th, 1886. In the discussion which followed, and in which Captain Creak, of the Admiralty Compass Department, Mr. Alexander Siemens, and Dr. Hopkinson took part, it appeared that in three ships, lighted on the single-wire system with direct currents, small but not unimportant errors in the compass, due to the lighting currents, had been actually observed. Since that time several cases have been reported to me of large passenger ships, lighted with direct currents on the one-wire system, in which as much as 4deg. or 5deg. of error on the compass has been produced by the electric lighting.

In the latest of these cases, a few weeks ago, an error of 4deg. on the north course was found when the light was put on. The light was put on and off several times with the ship's head north, and every time the same error was produced.

The precautions for security which I have to suggest are—

1. The use of the two-wire method exclusively (unless, which is now rarely the case, alternate currents are used).

2. A differential galvanometer on the two mains for the lighting current to show approximate enough equality of the out-going and in-coming current. A rough and cheap instrument (on the old telegraph "detector" plan) would, I believe, suffice, and would be valuable for the electric lighting system (independently of the compass question) to give timely warning of any faults or accidental contacts or failures of insulation sufficient to cause any considerable difference in the strength of the currents carried by the two mains.

3. Care that there is not magnetic "leakage" from the dynamo (as practical men, guided by Faraday's ideas, theory, and language, have now taught the scientific world to call it) enough to produce any compass-disturbance of practical moment. Captain Creak, speaking at the end of 1885, in the Society of Arts discussion previously referred to, said that in one ship the direct compass-disturbance produced by the generating machine was "felt through a distance of 55ft.," and across iron bulkheads, and that it was perceptible also in other ships of the Royal Navy electrically lighted on the two-wire system.

My impression is that the improved dynamos now made have much less of magnetic leakage than those made prior to 1886, but we still want information as to their disturbing magnetic effect at such distances as have to be considered in connection with the compass question.

4. To ascertain that there is no perceptible compass-disturbance, or if there is any to test its amount, the compass should be observed while the current through the dynamo is started and stopped, either by starting and stopping the dynamo itself or by making and breaking the circuit of the field magnets. This should always be done before the electric light installation is taken over from the contractors. It is best and most easily done when the ship is in dock, or lying steadily at anchor. On no account ought it to be delayed, in a new ship, till she goes out for compass adjustment. A determination of the amounts of the disturbance, if any, for all courses of the ship can be made by aid of my deflector without moving the ship. But a sufficient practical test may be made by first observing the effect of starting and stopping the current on the compass as it stands; then adjusting a small magnet placed on, or supported a little above the glass of the bowl, to deflect the compass about 45deg. first on one side and then on the other side of its undisturbed position, and in each case observing the effect of starting and stopping the electric current. This effect ought not to be as much as 2deg. in any of the three cases.

5. A small electric lamp may safely (and with very great advantage in most cases of electrically lighted ships*) be used to light the compass. The effect, if any perceptible, of its current on the compass ought to be tested in the manner described in No. 4.

* Those who know the trouble of keeping the best of ordinary compass lamps alight, for the steering compass on the bridge of some of our cross Channel steamers in a winter gale, will appreciate this advantage.

DISCUSSION (AUTHORISED ABSTRACT).

In opening the discussion, Captain CREAK said he was glad Sir William recommended the two-wire system, for that in itself was a great safeguard against disturbance. So far as his own experience goes, most trouble arises from magnetic leakage due to the employment of machines having considerable external field and placing them in positions with respect to the iron of the ship that such field was directed towards the compass. In one case, H.M.S. "Northampton," where three such machines were used, an error of 11deg. was produced when all the machines were running, and three correction tables were necessary.

Mr. ALEX. SIEMENS, as an advocate of the single-wire system, thought it quite unnecessary to use two wires, for in all his experience, extending over many ships fitted on the single-wire system, only one instance had occurred in which complaint was made, and in this case the wiring was done before the position of the compass had been decided upon, the spot eventually chosen being in close proximity to the leads. As a proof that the single-wire system could be made satisfactory, he mentioned that his firm make inquiries on all vessels fitted by them every time they come into port, in order to ascertain whether any inconvenience arises from the electric lighting apparatus; but with the exception above quoted no complaint has been made.

Referring to Mr. Bottomley's letter mentioned in the Paper, Mr. SIEMENS said the screening effect of the decks had been entirely neglected in the calculations there given.

A second case of disturbance had come under his notice by his being asked to inspect a ship fitted by another firm, and the maximum deflections produced were ½ deg. and 1½ deg. on the standard and steering compasses respectively.

As regards the position of dynamos he had found no appreciable effect at distances greater than 50 feet.

Prof. G. FORBES, speaking of H.M.S. "Northampton," said that the dynamos referred to by Captain Creak were placed in an iron room, and still the disturbance produced was very serious. From an examination of machines of the type there employed he found that the leakage mainly comes from the parts of the yokes near their junction with the cores, but he had reason to believe that in the more modern machines the leakage has been considerably reduced.

Prof. JAMIESON mentioned the case of s.s. "Bombay," in which the steering compass was disturbed 9deg.; the fault was traced to a wire about 4ft. from the compass, and remedied by running a return wire.

Mr. RAWORTH, in corroborating Mr. Siemens with regard to the great convenience of the single-wire system, gave additional details respecting the second case mentioned by Mr. Siemens. The compass was influenced by either of two converging wires running along lower passages, according as the needle was parallel to one or to the other. On examining the decks the iron was found cut away between the wires and the needle, and the defect was remedied by enclosing the former in 3in. iron pipes.

Major CARDEW described his experience in lighting binnacles electrically, as suggested by Sir W. Thomson in his Note, and although he carefully twisted the leading wires together the filament seriously affected the compass reading.

Sir W. THOMSON, in reply, said that caution was necessary in arranging lamps for lighting compasses, and in answer to Prof. Forbes expressed an opinion that alternate currents if used in such lamps would not demagnetise the needles. Referring to the screening effect of decks, he pointed out that Capt. Creak's observations proved them to be of little use in neutralising the external field of dynamos, and to be efficient the iron required to be very thick. The decks may, however, considerably reduce the action of currents on the compasses, especially where the circuits are completed between two decks; but when the wires pass from one deck to another the screening effect is much reduced. Although the conductors in the single-wire system may be placed so as not to affect either one of the two compasses generally used, yet it is very difficult to arrange that neither are disturbed, and as any disagreement between the two (especially as the difference may vary with the portion of the ship being lighted) further complicates the navigation, Sir William felt sure it would be far the best plan to adopt the two-wire system in all cases.

The discussion on Mr. Mordey's Paper, on "Alternate Current Working,' was deferred till the next meeting, on May 30th.

THE AMALGAMATION OF THE TELEPHONE COMPANIES.

The following circular has been issued by the Directors of the United Telephone Company:—

"The directors of this company have been engaged for some time past in arranging a scheme for the amalgamation of the company with the National Telephone Company (Limited) and the Lancashire and Cheshire Telephonic Exchange Company (Limited), the intention being to form a new company which should acquire the property of the three companies, the new company issuing its shares to the latter on the basis of £15 to this company, £6 to the National Company, and £1. 11s. 6d. to the Lancashire and Cheshire Company, those figures representing the then market price of the shares. As, however, the Postmaster-General objects to the licenses held by the three companies being transferred to the proposed new company, the formation of that company must be abandoned.

"The amalgamation of the three companies is now intended to be effected by the purchase of two of them by the third, the latter

Digitized by Google

company giving its shares as the purchase price. As the licenses held by the companies extend to the whole of the United Kingdom any one is sufficient to cover the business of all three companies when amalgamated.

"The purchasing company must obviously be the one whose shares are nearest to par in market price. The National Company most nearly complies with this condition, and it is therefore proposed that that company should absorb the Lancashire and Cheshire Company and this company.

"As, owing to legal considerations, the National Company's shares can only be taken at their par value, it is necessary to nominally reduce the figures originally proposed as the basis of the amalgamation, which will then stand as follows, viz. :—£12. 10s. for each share of this company, and £1. 6s. 3d. for each share of the Lancashire and Cheshire Company, the National Company's Ordinary Shares, representing the purchase price, being taken at par (£5).

"You will observe that the above amounts are simply the figures of the former arrangement reduced by one-sixth all round. The relative values of the interests of the shareholders of the three companies are therefore unaffected by the variation, the result being that the shares whilst of a rather less nominal amount will produce a corresponding higher rate of dividend, and may, therefore, be expected to command an equivalent price in the market.

"The new arrangement will take effect as from the 1st May inst., and power has been reserved to pay a dividend to the shareholders of this Company for the period ending April 30 last."

OBITUARY.

GASTON PLANTÉ.

It is with extreme regret that we have to record the death at the comparatively early age of 55 of M. Gaston Planté, which occurred in Paris on the 24th inst. For some years M. Planté's health has been in a precarious condition, and not long since he mentioned in a letter to ourselves that his sight had almost entirely failed him.

Gaston Planté was born at Orthez, in the Basses Pyrènées, on April 22, 1834. He received his scientific training at the Conservatoire des Arts et Metiers in Paris, where he afterwards obtained his first appointment as laboratory assistant to M. Ed. Becquerel. At a later date he entered the service of the eminent firm of Christofle et Cie. as chemist, and here he carried on the investigations into the nature of electric polarisation, which he had already commenced under Becquerel, and which subsequently led to his great discovery of the lead accumulator. M. Planté continued for many years to add to the number of cells in his possession; he studied their progressive formation with keen interest, and, as he had to rely chiefly upon the Bünsen battery for his charging current, the process was both tedious and costly. Many of his experiments on the discharge were of the most brilliant and even daring character, and there is no doubt that the weakness of sight to which we have referred was increased by, even if it was not altogether due to, repeated experiments of this description.

The results of these researches were from time to time communicated to the Académie des Sciences, or published in the various scientific periodicals. In 1879, just twenty years from the date of his first communication to the Academy, the whole of these Papers were issued in a collected form under the title of "Recherches sur L'Electricité." In this volume a vast number of experiments are described, many of which were carried out with a lead battery of no less than 800 elements. The "rheostatique machine," by means of which the potential could be still further raised, is one of M. Planté's most striking inventions, though it only occupies a few pages at the end of this book. By means of these appliances M. Planté was enabled to study the effects of currents of high potential and of discharges of great energy at a time when other *savants* were entirely dependent upon the limited possibilities of the primary battery. And at the very least it may be said that M. Planté made such good use of his opportunities that remarkably little has since been added to our knowledge in the class of work which he especially cultivated.

M. Planté was not one of those who seek to make their scientific discoveries a means of personal gain; indeed, so far as we are aware, he never at any time figured in the lists of the Patent Office. Yet he was by no means blind to the possibilities of the practical application of the lead battery, and amongst other suggestions for its use he referred at an early date to the electric light; although in an era before Swan and Edison were known, and when the dynamo was scarcely as yet a commercial machine, he was unable to foresee the full importance of the suggestion. Two years after the appearance of this volume, in October, 1881, the first actual commercial use of the accumulator took place, and—it is a fact perhaps not generally known—this was for train lighting upon the Brighton and South Coast Railway.

That same year M. Planté received the Diplome d'Honneur at the Paris Exhibition, and he was also made a Chevalier of the Lègion d'Honneur. A little later the Académie des Sciences conferred upon him the "Prix Lucaze," and he also received the Médaille d'Ampère from the Société de Encouragement pour l'Industrie Nationale. During the last few years of his life M. Planté devoted himself chiefly to the study of atmospheric electricity, which he did much to advance. About twelve months since he published a small volume of very great interest, under the title of "Phénomènes Électriques de l'Atmosphère," which was reviewed in *The Electrician* of August 3, 1888.

The honours which were showered upon M. Planté during the latter portion of his career did not induce him in any way to modify the quiet and retired life which he had led for so many years. Nearly his whole time was passed in his laboratory in the Rue des Tournelles, where, however, a kindly welcome was assured to every visitor, more especially to such as happened to take an interest in the pursuits in which his attention was absorbed. His modest and amiable character never failed to impress all with whom he came into contact, and his loss will bring a sense of keen regret to his numerous friends as well in this country as in his native land.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, May 31st.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "An Attempt to apply to Chemistry one of Newton's Principles." By Prof. DEMETRI MENDELEEF, D.Sc.

SATURDAY, June 1st.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "The Classification of the Sciences, Historical and Critical." By Prof. W. KNIGHT, LL.D.

MONDAY, June 3rd.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Town Hall, Westminster. "The Forced Percolation of Water through Concrete." By HENRY FAIJA, M.I.C.E.

TUESDAY, June 4th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Some Recent Biological Discoveries." By Prof. E. RAY LANKESTER, M.A., F.R.S.

THURSDAY, June 6th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Chemical Affinity." By Prof. DEWAR, M.A., F.R.S.

CITY AND GUILDS OF LONDON INSTITUTE OLD STUDENTS' ASSOCIATION.

7:45 p.m. Ordinary General Meeting at the Central Institution. "The Economical Use of a Primary Battery based upon the Recovery of Zinc." By T. G. NICHOLSON.

CHEMICAL SOCIETY.

The Electrician.

ublished every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

'THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

'THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

THE HALIFAX AND BERMUDAS CABLE.

Submarine Cables are by no means well represented in Parliament, and Members who meddle with them usually betray their extreme ignorance, or, as in a well-known instance, reckless hostility to the existing Cable Companies. But as regards the projected cable between Halifax (Nova Scotia) and Bermudas, the contract for which has lately been warmly discussed in the House of Commons, the critics are for once in a way entirely right and the promoters entirely wrong. Of the project, considered as a commercial undertaking, we will speak presently; but at the very outset the proceedings have taken such a questionable shape that the Government would have been justified, and perhaps well advised, if they had accepted Dr. CAMERON'S suggestion and cancelled the agreement altogether, as they had the power to do, instead of extending the term of grace in order to prevent the lapse of the contract. On the 9th inst. Parliament gave its sanction rather reluctantly to a subsidy being granted of £8,100 per annum for 20 years to the International Cable Company on their constructing a working cable between the above-named points, subject to capital being raised by the company amount-

Digitized by Google

ing to £100,000 within seven days of the approval of the contract by Parliament. Neither of these conditions has been adhered to, the International Company having transferred the benefits of the cable contract to a new concern, the Halifax and Bermudas Cable Company (Limited), the time allowed for raising the capital being extended to 9th June. This has been done with the Treasury's sanction, and the natural result was that on Tuesday last some very strong protests were made against this mode of evading, or at all events seriously modifying, an agreement deliberately sanctioned by Parliament. We are inclined to agree with Dr. CAMERON that there is something farcical in gravely discussing the details of a contract the chief features of which can be altered by the Treasury the next day.

But we may leave the House of Commons to settle this technical objection with the Secretary to the Treasury as best it can. What we wish to direct attention to particularly is the curious circumstance that a transfer of interest was allowed to take place at the initial stage of the transaction without apparently arousing the least suspicion that the scheme was financially unsound. The transfer itself looks bad; the application for an extension of time to raise the capital still worse. And when we come to examine the prospectus of the new company, issued on the 24th inst., there appear good grounds for believing that Parliament might not have sanctioned the cable contract had that document been in the hands of Members on the 9th. From one point of view no doubt the Treasury made a good bargain, although, as was pointed out at the time, the subsidy is a large one for an outlay of what it is supposed will not exceed £100,000. Still, the Government avoid all the risk of the operation; they pay no subsidy when the cable is not working; and they reserve the right to send messages over the line at their own figure, which, following precedent, will probably be half the ordinary public rate. But on the other hand the guarantee that the cable will be maintained in working order even if successfully laid is remarkably slight, seeing that on the Board of Directors of the new Company there is not a single name known in the great cable-laying profession. Strange to say, moreover, the name of the firm that is to construct and submerge the cable is nowhere mentioned in the prospectus. If the object of the Government is, as we take it to be, to secure electrical communication for strategical purposes with one of their most important naval stations, the precautions taken for ensuring its efficiency are certainly of the slenderest character.

There are no doubt grave objections to the Government themselves undertaking a task of this kind, although it is one of national rather than of commercial importance. But the alternative course would have been to frankly place the matter in the hands of competent people whose reputation and standing would have insured the success of the operation and its permanent maintenance. The terms might have been different; but no terms whatever can be advantageous which may entice the nation into a position of false security as regards its naval and military stations. Where this cable is to be laid the waters are known to be deep and the current strong; and every appliance that experience and capital can command will probably be needed to keep the communication intact. In fact, it is simple folly for a company to undertake the maintenance of a submarine line which has not a sufficient mileage of cable to enable it to keep one or more repairing steamers. A single repair may be so costly as to be seriously embarrassing, because if it were necessary to charter a steamer in England to repair the Halifax-Bermuda cable the expense might soon run up to five or six thousand pounds, and it is quite evident that if, say, two repairs were required at intervals of a year or two the result would be disastrous. We fail to discover any elements entitled to command confidence on these essential points, either in the management of the new company or the manner in which its capital is being asked for.

One other point the Government ought to have taken more pains to inquire into than they appear to have done. The maintenance of the cable will depend largely upon its commercial prosperity, and any failure in this respect would be ill-repaid by impounding the Company's £15,000 caution-money. On a review of the conditions attached to this scheme we are satisfied that its prospects of commercial success are very remote indeed. The twenty years' subsidy of £8,100 per annum is to be used exclusively to provide interest and a sinking fund for the redemption of the capital. If, therefore, the traffic should prove insufficient to maintain and repair the cable, the subsidy will lapse, and cannot be utilised. And on a very liberal estimate we are unable to see where the traffic is to come from that will cover the working expenses and provide for contingencies; £5,000 a year probably will be the outside figure at which the traffic over such a line can be safely calculated upon, whilst the cost of the two stations could hardly be less than £4,000, and the London management £2,000, a year, making a total of £6,000 a year, exclusive of the cost of repairs, as to which further reference is made below. Unless we are greatly out in our reckoning the working loss is therefore certain to be considerable, while the shareholders will have to rely for their dividends solely on the subsidy, which will cease the moment anything happens to their cable. This is not a pleasant prospect for investors; but that is their affair. As regards the nation, however, the case is different and far more serious. The life of the Halifax and Bermudas cable, and the safety in time of war of a vital point in our circle of naval strongholds, are made to depend on the earnings of a line of cable which at best cannot be profitable, and the result may possibly be its speedy and ignominious abandonment.

LEGAL INTELLIGENCE.

King, Brown and Co. *v.* The Anglo-American Brush Electric Light Corporation (Limited).

Counsel were heard before Lord Trayner in the Court of Session on the 22nd inst., in the action for reduction of a patent right, brought at the instance of King, Brown and Co., Rosebank Electric Works, Edinburgh, against the Anglo-American Brush Electric Light Corporation (Limited). The evidence was reported in *The Electrician* when the case was before the Court last session. The pursuers were represented by Mr. A. Graham Murray, Mr. Dickson, and Mr. Daniell; and the defenders by the Dean of Faculty (Mr. J. B. Balfour, Q.C., M.P.), and Mr. Jameson.

Mr. GRAHAM MURRAY, for the pursuers, said he wished to recall to his Lordship the genesis of this action. Although he was there as pursuer he was at the same time in one sense really and honestly defending himself. This action was, so far as the Scottish Courts were concerned, the sequel to another action raised before his Lordship. In the condescendence in this action it was set out that the defenders had frequently threatened the pursuers with proceedings for infringement of their letters patent, and that in consequence the pursuers had lost orders and suffered damage. The previous action was brought by the pursuers against the defenders, and founded both upon common law and certain provisions of the recent Patent Act, was directed to have the Brush Company interdicted from publishing threats against the pursuers. The defenders put in defences, and said, "You cannot have the common law, and the provisions of the statute says you shall only have the right to bring the action provided the other party has not taken steps to put a stop to any infringement. His Lordship was with the pursuers in the view that they could raise the whole question of the patent in that action; but the Inner House were of opinion that a declarator of reduction of the patent should be brought. This was accordingly done, this action being raised. He was thus, though the pursuer, really defending himself and his legitimate business. The learned counsel then entered into a historical explanation of the progress of electric science, and the various systems of producing electricity. He explained the different shunt arrangements—shunt, series, and series-shunt, and by

Digitized by Google

the use of models of dynamos made clear the uses and the value of these various systems. He explained the difference between potential and electromotive force. Coming to the question at issue, he said the reasons they asked for a reduction of the patent were these. They said, first of all, that the patent is bad upon the interpretation of it in respect of the commutators, because there was a claim for commutators in the final specification which is not covered by the provisional specification. They also said that taking the claims together on the commutators, his friends were in this difficult position, that either they were anticipated—being matter of common knowledge at the time, or else what little improvements there might be were such as were really not patentable. They also said that one part of the commutator claim was undoubtedly anticipated by Varley. They also said that the patent was bad in respect that the commutator claim was bad, because there had been the same sort of commutators in actual use before the patent, the use being both in Manchester and in Varley's own machine.

LORD TRAYNER: I understand your argument to be this. The provisional specification refers to a certain form and character of a commutator, but purely with regard to its form and the mode in which it may be, speaking quite popularly, easily repaired. The final claim (4) introduces an element of great importance in electrical science—that is to say, to cut off the current at a particular point where the cutting off is valuable to the work. That is not necessarily an implication involved in the original specification. The one is form, and the other is effect.

Mr. GRAHAM MURRAY said that was precisely his argument. In concluding that part of his argument Mr. Graham Murray said that if the patent was bad upon the commutators it was bad altogether—there was no patent at all; and therefore if he was right in this connection the case of the other side was at an end, no matter what decision there might be with regard to the question whether the real interest between them had anything to do with the commutators or not. Passing to what he said was the more interesting part of the case to them, namely, the question of series-shunt winding, counsel said his points were two in number—first, prior publication by Varley's specification, and secondly, prior use by Varley's machine. He would say that undoubtedly Brush's machine was a very great improvements but it was an improvement which for the practical purpose for which it was now used was not anticipated either by Brush or by Varley, whichever of them invented it. In fact, if he might be allowed to make use of a vulgar term, it was a gigantic "fluke," and the question was who "fluked" it first? (Laughter.)

LORD TRAYNER: What does that mean?

Mr. GRAHAM MURRAY said there was no word in the English language which conveyed the same meaning. There was not the slightest idea in Brush's case of the use to which that could be put, and the historical reason for that was, that at the time of both Varley's patent and Brush's patent the problem of incandescent lighting had not been solved, for the reason that there had not been discovered a suitable lamp owing to the want of suitable material. It was quite well-known that they could produce incandescence, but the difficulty was to find a suitable material that would resist the incandescence without being rapidly consumed in the process. That difficulty was eventually obviated. Having quoted from the specification, counsel said defender's witnesses wished to make out that the words "other applications of a permanent field" in the specification was a fair way of saying that one of the advantages they had in view was constant potential. Mr. Brush, however, was too honest for them on that point. He was rather an unfortunate witness, for when asked to explain the words "permanent field" in the specification, he said, "the words 'permanent field' refer to the permanent field of the machine, which exists both in the shunt-field arrangement and in the series-shunt field. These words do not mean an unvarying field, but they mean a permanent field of unvarying polarity." That there should be other useful applications of a permanent field besides electro-plating counsel did not deny, but he held that the securing of constant potential was not one of them. There was not, he maintained, any indication in the specification itself of their wishing to secure constant potential at all. Constant potential was not even the necessary outcome of series-shunt winding, but required a great deal more arrangement and a great deal more discovery. He admitted that a series-shunt machine could be constructed from Brush's description. If, however, they did construct such a machine, it would be an accident whether they got constant potential or not. The great advantage of the series-shunt arrangement—namely, the facility for getting constant potential with such a machine—was utterly unknown to Brush, as, he also admitted, it was unknown to Varley. The real merit of the invention had come by chance, and the question was which of these two men was the first to indicate the method of winding the machine, it being common ground that neither of them really knew the great effects to which that would lead. It had, he argued, been shown that Brush did arrange a machine by which, by accident, he discovered a method of winding which eventually led to an ending which he did not foresee. And why should not the same be the case with Varley's? He then proceeded to discuss the question whether that method of winding was disclosed in Varley's specification. He quoted the evidence of a number of witnesses with special reference to Varley's specification, and contended that he had shown that the description in Varley's specification was true of series-shunt. It was quite evident that it was not pure series winding which was suggested by Varley. First of all they cover two branches or circuits, and the same thing is quite true of pure shunt, because pure shunt would be inconsistent with the description on line 43, "When the electric light is being produced the greater portion of the electricity passes from the circuit of less resistance, which I term the electric light circuit, maintaining the magnetism of the magnets and producing the light." That would be absolutely untrue of a pure shunt arrangement, because the electricity of the electric circuit has nothing to do with the magnets and never went there.

LORD TRAYNER: The description by Varley is not consistent with either series or pure shunt for, I suppose, this reason, that this mode of producing his shunt is to wrap the soft iron magnets with two separate wires, one of larger resistance than the other. It is utterly absurd to describe either pure shunt or series-shunt.

Mr. GRAHAM MURRAY said that was so. Notice had been given them in the cross-examination of Mr. Imrie that the question of separate excitation would be raised, and he quoted evidence to show that Varley's patent was not separate excitation but series-shunt, the method being to wrap two wires round the magnets. At the time of the patent there were, as Varley said, several well-known ways of maintaining the magnetism of the magnets, but the method Varley preferred was not well known—that of wrapping two insulated wires round the magnets. The reason why Mr. Varley had not claimed the series-shunt patent was, as he himself explained, because he was afraid of coming into collision with his brother, who had made a disclosure. The actual fact was that that disclosure was not series-shunt but something resembling induction. Apart from that this arrangement of Varley's was a valuable one for another invention which had long gone into oblivion, but which at the time bulked very largely in Mr. Varley's mind, namely, a peculiar form of lamp. That lamp had not been a practical success. At the same time he wanted it to go, and it was necessary for its proper working that he should have that system of series-shunt winding. While the lamp had gone into oblivion the system of winding had come to be used for something of far greater importance. The lamp was an arc lamp with a motor, and the carbons were kept in proper position by motion in the lamps, and that lamp motion was worked by electricity, and the electricity devoted to the maintenance of that lamp motion was put into the circuit of greater resistance, or the shunt circuit. Mr. Swinburne said very clearly that none of the other systems of winding would have worked that lamp. It was quite impossible to reach the result of putting series-shunt out of the way by a process of destructive criticism, as had been attempted by his friends on the other side, and in which they had failed. They began with the idea that Varley was describing something, and if they followed his directions explicitly they arrived at series-shunt, for the very good reason that they could not arrive at anything else.

Mr. Graham Murray had not concluded his speech when the Court rose.

THURSDAY, MAY 23.

The hearing of counsel in this action was continued before Lord Trayner in the Court of Session on Thursday.

Mr. GRAHAM MURRAY (resuming his argument on behalf of the pursuers) took up the question of anticipation of Brush's patent by Varley's machine, made by Siebe and Gorman. There was no doubt that that machine had got two windings. There was no doubt that it had an appropriate commutator, and nobody could say that that machine could not be used in five minutes, if it were in working order, as a series-shunt machine. In fact, the whole thing was there. There was nothing wanting that was wanted in a series-shunt machine. The criticism of it by the other side was that the connections were all left disconnected—that was to say, the wires were broken off at the terminals, and as no person could have connected it properly, it was not a series-shunt machine. Using a model of the machine, he showed that that contention was absurd. The next thing that was quite clear about the machine was that it was perfectly proved that it was actually used. The eye-witnesses to the use of the machine were four in number—Gorman, Meyer, Garnish, and Varley himself. It was quite clear that machine was built upon that specification, and, therefore, if that machine was series-shunt surely that was much better evidence than any amount of criticism upon the specification could possibly be.

LORD TRAYNER: Strengthened by the fact that the man who wrote the specification, and had his machine constructed according to it, had constructed a machine which an apprentice boy on the same specification twenty years afterwards exactly copied.

Mr. GRAHAM MURRAY: Exactly so. Having read extracts from the evidence of Gorman, Meyer, and Garnish, from which it appeared that the machine had been used to produce light for the purpose of conducting experiments in a water-tank, Mr. Murray said that the result of the evidence of these three witnesses was this—that they remembered the machine being used. They remembered that the lamp had only one wire to it and only one wire away from it. They remembered also that it was noticed that the magnetism greatly increased when the lamp was lighted and decreased when the lamp was out. They remembered that the power of the magnetism did not disappear when the lamp was lighted. There was a considerable amount of magnetism in it, as evidenced by the sparking of the brushes. Taking that with the state of the machine itself, it seemed to the pursuers that that entirely excluded any idea of the machine being coupled in any but the way in which it would be the most natural to couple it in order to make it work as series-shunt. They had it distinctly said by Mr. Meyer that upon one occasion they used it without the fine wire being connected. When so using it as pure series it did not answer, and they used it another way; so that whatever the way was he took it as a way in which the fine wire winding was utilised, and that being so there was an end of pure series. Supposing it was used as pure shunt the same observation applied. What was the use of the thick wire? None. Next, they came to separate excitation. His lordship would remember that separate excitation of that machine was entirely excluded by the existing commutator, because they had all the bits of the commutator connected for series in one continuous electric circuit. Therefore, unless the commutator connections had been entirely altered they could not have worked that machine by separate excitation. Dealing with the allegation that the machine was double-shunt, counsel said nobody has yet suggested what conceivable use that double-shunt would be. He looked in vain in the proof for that. As a matter of fact, none of his learned friend's witnesses really suggested that it was double-shunt until they came to Prof.

Digitized by Google

Perry. That was just an heroic effort on the part of Prof. Perry to try and get out of the dilemma he was in about what had been observed of that machine. He got out of it theoretically by suggesting an arrangement by which these particular things might have been observed which were observed, and yet that the machine should not be series-shunt wound; but then in order to do that he had to suggest a key which as a matter of fact did not exist. Counsel then referred to the testimony of Mr. Varley. Mr. Varley was of course in one sense an interested witness. It was not unnatural that he should have a very paternal pride in his own invention, and of course he had taken up very strong views about it. His lordship would no doubt see that Mr. Varley was speaking the truth. If Mr. Varley was speaking the truth there was an end of the whole matter. In his evidence he said, "I had a machine constructed in accordance with my specification; it was connected as a series-shunt machine as described in my specification." If that was true there was an end of saying that that machine was not series-wound.

LORD TRAYNER said that the machine itself, looked at, showed that it was series-shunt wound. That was to say, it had two wires of different resistances. There was no doubt about that But the question rather was whether it was so coupled up as to be used as a series-shunt machine, or whether it was so coupled as to be used otherwise. There was also the additional observation that a series machine and a shunt machine being known, the reason why two wires were put upon the magnets was for the purpose of trying something different from a separate shunt or a separate series.

Mr. GRAHAM MURRAY said that of course the far-reachingness of the invention was not seen, but so far as the invention consisted in merely trying the two things together it was not an unlikely thing for a man to do.

LORD TRAYNER: So far as the potentiality of the machine was concerned Mr. Varley and Mr. Brush were in *pari passu*.

Mr. GRAHAM MURRAY: Yes. There was, continued counsel, another thing that helped Mr. Varley, and that was the sketch produced by him at the proof of a machine constructed according to his specification. It was certainly a very good memorandum of how that particular machine was coupled. There was no doubt as to the authenticity of the sketch in Mr. Varley's book, and there was also no doubt of what the sketch meant. The sketch was originally done in pencil and it was inked over. The only thing that remained was whether the drawing then was a sufficient disclosure in law. In the first place he used it as being a very good commentary of what the specification truly meant. There was no doubt as to the disclosure so far as the specification was concerned; and if the only result of following the specification was to construct a machine such as they had there, there was an end of the case, because it was practically proved that such a machine would be constructed. But assuming that the specification itself would not lead you to construct that machine then he said there was such use as in terms of law is public use. Very little use would do to invalidate a patent, and in support of this he referred his lordship to the cases of Carpenter *v.* Smith and Stead *v.* Williams. The use of the machine in Siebe and Gorman's yard was clearly public use. Upon the grounds he had stated he submitted the patent of the defenders' was bad.

LORD TRAYNER said there was one point in the case he should like to hear Mr. Murray upon. Suppose Mr. Varley and Mr. Brush, in equal ignorance of the eventual use of that machine, had both invented a machine, either simultaneously or the one after the other, for the purpose, say, of electro-plating. Suppose, further, that two or three years thereafter it occurred to Mr. Brush that although he had not seen it before that was the very machine for incandescent light, and he then patented it. Did the existing machine for that new purpose give him a patent?

Mr. GRAHAM MURRAY: Certainly not.

LORD TRAYNER: Is it quite certain?

Mr. GRAHAM MURRAY replied that it was. In the case, for example, of a machine for flattening silk there might be a patent for that machine if it were employed for flattening iron; but certainly if a man took a machine by which electricity was produced he could not say, "Having used the production of electricity for one object I will now use the electricity which is so produced for another object, and by that means obtain a patent," there being no new invention. Of course he quite well saw that there might be patentable matter left for improvements even upon the series-shunt winding.

LORD TRAYNER: If there were an alteration of the machine its application to a new purpose of course is patentable; but taking the machine as it exists, was the mere application of it rather than the thing itself a patentable right?

Mr. GRAHAM MURRAY: I believe there is law upon it. I have no doubt about the fact.

LORD TRAYNER: I have an impression, but may be quite wrong, that if the application is a perfectly new idea, and one of great utility and merit, it might be patentable.

Mr. GRAHAM MURRAY said his point was that if it were the application of a machine he quite agreed. But then it was not the application of a machine, it was the application that was made by the machine of the electricity. He quite saw that if suddenly they could find out that that machine which created electricity could by doing something else make something else quite different, they might have a new patent.

LORD TRAYNER: As you turn the machine to a totally different use?

Mr. GRAHAM MURRAY said, Yes; that would be really using for the first time a certain mechanical arrangement to produce a new thing different from its original production. Of course his lordship saw that here electricity would be produced precisely in the same way, but simply turned to another purpose.

LORD TRAYNER: Perhaps that is the distinction.

This ended the case for the Pursuers.

(To be continued.)

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

(Continued from page 14.)

150. *Intensity of Field at any point on the Axis of a Solenoid.*—The results already derived will afford sufficient ground to work upon in order to show how the field at any point on the axis of a solenoid is determined. In the two expressions for the field at the centre and at either end, if we consider only those factors which alter in value according to the position of the point on the axis, we shall be able to trace the general law for any point. On examining these expressions we find that

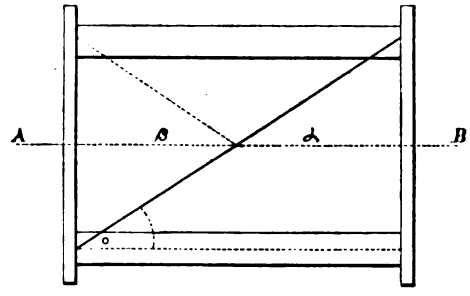

Fig. 153.

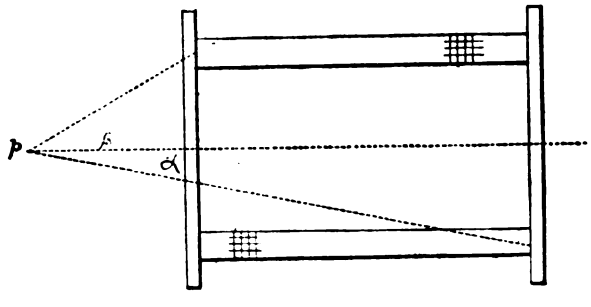
the factor $2\pi C_1$ occurs in both, and therefore the remaining factors depending on the position of the point considered are

$$\frac{2l}{D} \text{ at the centre,}$$

and

$$\frac{l}{R} \text{ at either end.}$$

Now the ratio of the length of the solenoid (l) to the diagonal (D) is the cosine of the angle (0) between them (Fig. 153), and it is evident that the angle 0 is equivalent to the angle α. Further, if a line is drawn from the centre to the other end of



Fig, 154.

the solenoid, as shown, it is evident that the included angle β is symmetrical with the angle α and equal to it.

We have, therefore,

$$\frac{2l}{D} = 2\cos\alpha = \cos\alpha + \cos\beta.$$

This is for the field at the centre of the coil; and now if we consider the field at one end we find in a similar manner that the ratio of l to R (Fig. 149) is the cosine of the angle between these lines. Generalising these results, it is not difficult to see that the field along the axis *within* the coil depends upon the sum of the cosines of the angles formed on each side of the point wherever that is situated on the axis. For instance, as the field is considered at points further away from the centre towards A (Fig. 153), the angle α becomes less and less while β becomes greater; and finally, when the point is taken at the end of the coil, as in Fig. 149, the angle β has increased to 90deg.

Digitized by Google

where its cosine is zero, while α has become equal to the angle enclosed between the lines l and R, as we have seen above.

Replacing the constant factor $2\pi C_1$, and putting for C_1 its equivalent (Cn divided by l), we have the result that the intensity of field at any point on the axis *within* the coil is equal to

$$\frac{2\pi C n}{l}(\cos\alpha + \cos\beta) \text{ C.-G.-S. units.}$$

Now at the end of the coil the cosine of β is zero, and beyond this, viz., *outside* the coil, its cosine changes in sign. The field at any point outside the coil on its axis (such as at p, Fig. 154) is, therefore, proportional to the *difference* of the cosines of the two angles instead of their sum as above. The angle α in this figure is shown on the other side of the axis for convenience. It is evident that it is identically the same as when indicated above the axis in the same way at the point p. This may now be applied to some practical example. It is best to take some definite size of solenoid and calculate the intensity of field at various points along the axis, and from these results plot a curve showing the way in which the field varies. By this means an insight is obtained into the relative strength of field at various points on the axis of such a coil. Take a solenoid eight centimetres long and wound with 100 turns of wire, the mean radius of the coil so wound being one centimetre (Fig. 155). Say a current of 1·27

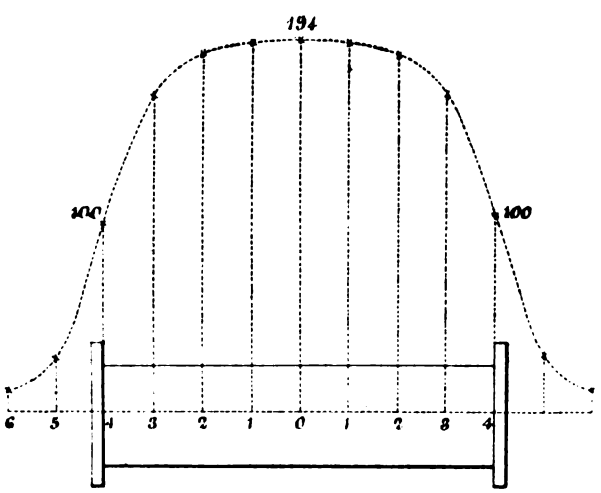


FIG. 155

amperes is passed through this winding, then the constant quantity

$$\frac{2\pi Cn}{l} = \frac{2\times 3{\cdot}1416\times 1{\cdot}27\times 100}{8} = 100$$

the current being expressed in C.-G.-S. units. The factors which vary according to the position of the points on the axis have now to be determined, and as the distribution of field is symmetrical on each side of the centre it is only necessary to make the calculations for one side. The angles themselves need not be determined, but simply their cosines, and this only involves in each case finding the value of the hypothenuse of a right angle triangle of which the other two sides are known. We have at the centre two equal angles, the cosine of each of which is

$$\frac{4}{\sqrt{4^2+1}} = \cdot 97,$$

the denominater being the hypothenuse, and found by extracting the root of the sum of the squares of the other two sides. At the centre of the coil the field is, therefore,

$$100\times 2\times \cdot 97 = 194 \text{ C.-G.-S. units.}$$

Now calculate the field at points on the axis one centimetre apart. At one centimetre distance from the centre the two angles are different, their cosines being found in the same way as the above, and added together, viz. :—

$$\frac{5}{\sqrt{26}} + \frac{3}{\sqrt{10}} = 1{\cdot}93.$$

The field to this point is, therefore,

$$100\times 1{\cdot}93 = 193 \text{ C.-G.-S. units.}$$

Similarly, at two centimetres from the centre the field is

$$100\left(\frac{6}{\sqrt{37}} + \frac{2}{\sqrt{5}}\right) = 188 \text{ C.-G.-S. units.}$$

At three centimetres the field, similarly calculated, is equal to 169 units. Now at four centimetres from the centre we arrive at the end of the coil where one angle becomes 90 deg. and its cosine nil, the cosine of the remaining angle being

$$\frac{8}{\sqrt{65}} = \cdot 99.$$

The field at the end of the coil is, therefore,

$$100\times \cdot 99 = 99 \text{ C.-G.-S units,}$$

or a little more than half that at the centre. It will be observed that the field diminishes very rapidly at this part of the axis. At five centimetres from the centre the point is outside the coil, and the difference of the cosines is therefore taken. The field is therefore

$$100\left(\frac{9}{\sqrt{82}} - \frac{1}{\sqrt{2}}\right) = 28 \text{ C.-G.-S. units.}$$

Similarly, at six centimetres from the centre the field is equal to

$$100\left(\frac{10}{\sqrt{101}} - \frac{2}{\sqrt{5}}\right) = 10 \text{ C.-G.-S. units.}$$

These values plotted give the curve shown in the figure, which therefore graphically represents the variation in intensity of field along the axis. It will also be noticed by the foregoing example that when we have a given strength of current per unit length of solenoid (Cn divided by l constant), the variation of field along the axis depends only upon the geometrical dimensions of the coil; that is, on the relation between the mean diameter and length of the solenoid, and not on its actual size as a whole. For example, the curve above plotted (Fig. 155) for a solenoid whose length is four times its mean diameter, will be precisely the same for solenoids of 2, 3, 10, or any number of times the actual size of the above, provided they have the same relation between length and diameter, and carry the same current per unit length, irrespective of the size of the wire composing the coil.

[With this section the Ninth Chapter of the present series is concluded. These chapters will be issued in volume form in a few months' time, when also the series will be resumed in the columns of this journal.—ED. *E.*]

ALTERNATE-CURRENT WORKING.*

BY W. M. MORDEY.

(Continued from page 67.)

PERIODICITY.

Some confusion is caused by the various ways in which rates of alternation are expressed, it being often quite uncertain whether periods or half-periods are referred to when "alternations" or "reversals" are spoken of. This confusion should be avoided by using the term "period," which has, I think, always been taken as expressing the complete cycle, or the changes undergone by a simple rectangle or elementary armature rotated from zero through a complete revolution in a simple magnetic field. To save confusion I always write it thus, $\curvearrowleft$; and I would suggest that this sign be used unless a better one be forthcoming, and that we agree to speak of periods, instead of alternations or reversals, and of periodicity instead of frequency or rates of alternation or of reversal.† Prof. Silvanus Thompson informs me that formerly a somewhat similar difficulty arose in regard to sound, and that confusion was avoided in the science of acoustics by giving the word

* Paper read before the Institution of Electrical Engineers on Thursday evening, May 23, 1889.

† This sign may be written something like, but rather larger than the algebraic sign ($\sim$) for "difference."

Digitized by Google

"vibration" the definite meaning of the double motion which it now possesses, the French tuning-forks being stamped with the letters "V.D." (*vibration double*) after the number.

The subject of periodicity is becoming a very important one, for both commercial and scientific reasons. It urgently demands settlement in the interests of the whole industry. The very wide differences found in scientific opinion on this matter and in the practice of the various manufacturers must lead, and are indeed now leading, to much confusion and inconvenience. As things stand at present great uncertainty exists not only as to what rate is the best, but whether transformers, arc lamps, or other apparatus made by one maker, for a given E.M.F. or purpose, can be used on a circuit fed from an alternator constructed by another maker. It might be suggested that some joint action should be taken by manufacturers and others concerned in the direction of securing uniformity; but there are arguments against such a course, the principal one being that probably each maker believes he has good reasons for his own practice.

I venture to think there is no right or wrong periodicity What may be best for one set of conditions, or with one type of apparatus, may not be best for another. Or perhaps it would be more correct to say that there is a right periodicity, and that there are right and wrong apparatus; but this is rather a delicate subject.

The relative advantages of high or low periodicity must be considered as bearing on the five main divisions of apparatus used. Taking these in their natural order, they are :—

1. Prime Motors. | 3. Conductors.
2. Alternators. | 4. Transformers.

5. Lamps, &c.

Each of these divisions contains matter in relation to periodicity which in the near future will probably form the subject of many Papers, as the various subjects become better understood. I am not able to do more than touch briefly on each, in the hope that my remarks may lead to the expression of the views of others, and to some approach to uniformity.

1. *Prime Motors.*—At present questions affecting prime motors do not usually bear directly on the subject of periodicity. The only exception is the Parsons steam turbine, with which there seems to be no great difficulty in using a simple two-pole machine, thus making the number of revolutions and of periods the same. There may be found some want of flexibility as regards changes of size or output with such turbines, as, from the nature of the case, speed can only be varied by very large amounts. Thus, for instance, if 100 ∿ are required, there is no choice except between a two-pole machine at 6,000 revolutions per minute and a four-pole machine at 3,000 revolutions. This is, of course, on the assumption that the alternator is driven direct. If indirect driving is resorted to the difficulty is much reduced. It is unlikely, however, that the bearings of a steam turbine would work satisfacterily except with direct driving.

2. *Alternators.*—It is not allowable to doubt that the divergencies in periodicity found in practice are to a great extent the result of development and survival of what has been found to give the best results in each case; but from an examination of the machines in use it is very difficult to trace any common line on which action may be supposed to have taken place. It is true that the general tendency has been towards a reduction of the periodicity, but the causes which are responsible for that tendency are very obscure. I have seen large and small machines, made at the same time by one maker, in which the number of coils was the same, although one had to run at about 2,000 revolutions a minute and the other at less than half that rate of speed. At least one of these was wrong. For the purpose for which these machines were made the very high periodicity was almost unobjectionable in the small machine, but in the large ones it led to disaster.

It is a common mistake to suppose that high speed of driving, or high peripheral velocity, are necessarily connected with high periodicity and with large output. Of course any given machine, if run at a higher rate of speed than its normal one, must have a proportionately higher periodicity, but will not necessarily be capable of a greater output. It is quite possible to design a high-speed machine to give a low periodicity, and *vice versâ*. Perhaps the impression has arisen because with most alternators it is not possible or desirable to place the successive poles very close together on account of the magnetic leakage.

For machines with iron in the armatures it might be expected that the magnetic and electric losses, as well as the very considerable self-induction and consequent variations in the effective potential difference with changes of load, would lead to the reduction of the periodicity; but experience does not seem to have always led to this result. The lowest periodicity (42 with the Zipernowsky machine) and the highest (132 with the Westinghouse machine) are both found in alternators having iron cores. What is the reason of this great diversity? The machines have many points of resemblance, and yet one is run at more than three times the periodicity of the other. Not having seen the American machine I can offer no opinion based on personal observation; but of the Austrian alternator I can say that, in my opinion, it would not be advisable to increase the rate.

In a communication from Messrs. Ganz and Co., published a few days ago,* Mr. Zipernowsky says that the low periodicity used was chosen on principle to enable them to couple their dynamos parallel. He very cogently adds, in justification of this: "At present no practical electrician will hesitate to acknowledge the coupling of dynamos in parallel circuit to be a vital question of any parallel system of central-station distribution."

This bears out very completely my contention that the periodicity is governed in most cases by some special feature of the type of apparatus. Zipernowsky has had to go down to 42 ∿ to get his iron-cored alternators to synchronise, and for no other reason; for his statement is that synchronous action was "not a secondary result, but just the end we were aiming at," and he acknowledges that there are disadvantages connected with this low rate in other parts of the system.

But Westinghouse with 133 ∿ and Lowrie-Parker with 80—both having iron cores—can run parallel, the former with not less than half-load, the latter, as we now know, with any load; and I think I could run parallel without iron and at any load and periodicity, so that Mr. Zipernowsky's only reason fails to justify his action, except as regards his own particular apparatus.

Prof. Forbes recently stated that the exhaustive tests made in America with the Westinghouse apparatus had shown that there was no reason for reducing the rate of alternation, which is the highest now in use. This is very important, and it is to be hoped that some account will be given of the nature of the trials and of the results obtained. Mr. Ferranti, who at one time used very high rates, has for some time been using 80 ∿ at the Grosvenor Gallery, and has fixed 68 ∿ for the Deptford machines. I shall not be surprised to see him increase this before long.

In my own machine the periodicity is 100, which I believe is, on the whole, the best rate; but if it be required to do so for any special purpose there would not be much difficulty in changing it. The pole faces can be altered in number and in size by merely altering the pattern; the field winding, being in a single coil, would be equally simple and equally efficient for any periodicity. Even with a large number of poles placed close together, as would be required for a high rate, magnetic leakage would not increase. The size of the machine would not be sensibly affected. The armature would certainly be rather more costly for a high rate, as a greater number of coils would be required; but the efficiency, output, and regulating qualities would remain practically the same. Regarding this machine I think I may say that periodicity is not a question of the first importance. As far as I am concerned it is other divisions of the distributing apparatus that determine the rate at which it is desirable to work.

The bearing of the form and arrangement of any alternator on the best periodicity for that alternator is a very close one. The question cannot be settled on general principles.

I have referred elsewhere more fully to the conditions as they affect regulation under varying loads, parallel working, and other points in connection with alternators; and, as an appendix (*see* p. 20), I have quoted some observations made recently at the Institution of Civil Engineers during the discussion on Mr. Kapp's Paper, "On Alternate-Current Machinery," and not yet published.

I now pass on to the next division of the subject.

3. *Conductors.*—The choice of a suitable periodicity depends also to some extent upon the conditions as they affect the conductors.

The effect of rapid alternations in virtually increasing the resistance of conductors has been brought before us in Sir William Thomson's Presidential Address, and it becomes necessary to recognise clearly what practical limitations are imposed by this effect.

My attention was drawn to this matter two or three years ago, when I was called upon to examine and report upon an installation of about 1,000 100-volt lamps supplied directly by an alternator working at about 150 ∿. It was found that there was a very serious drop of potential in the conductors, and in consequence of this, the lamps could not be maintained at full power. On examining the circuit I found the cables were of ample size, and that the loss could not be explained in the usual way. As a result I came to the conclusion that it was to be accounted for only by some kind of inductional action, due to the alternating current, and I advised that a direct-current dynamo should be put down in place of the alternator. This was done, and with a perfectly satisfactory result. The lamps were for the first time run at their proper power, and no further trouble was experienced.

At that time I was, like most other electricians, a disbeliever in alternating currents, which I vaguely regarded as essentially unsatisfactory. I think there was a more substantial basis for this opinion than is now generally admitted. Alternating currents as

* *The Electrician*, May 10th, 1889, p. 16.

Digitized by Google

then most often used were not satisfactory ; and if great care is not taken at the present time some of the old difficulties will be encountered, with the result of unnecessarily discrediting the transformer system of distribution.

From Sir William Thomson's Address, and from some further information he has kindly sent me, I have worked out and tabulated some figures showing what restrictions are imposed by the virtual increase of resistance of solid conductors with alternating currents, as bearing on the question of periodicity.

Sir William Thomson gives some figures for a periodicity of 80, to which I have added some columns giving diameter in inches, sectional area, and the current which the practicable sizes will carry, taken on the basis of 450 amperes per square inch, because that density gives *1 per cent. loss per mile* with 2,000 volts. It also gives about *1 per cent. loss per 100 yards* with 100 volts, or, more exactly, 1·15 per cent. I have also given the number of watts at 2,000 volts and at 100 volts for each size, to show the limits for ordinary primary and secondary working with this density. These figures are given for 80, for 100, and for 133 ∿, the diameters of conductors for the same percentage increase of virtual resistance over ohmic resistance being in the inverse ratio of the square roots of the periodicities.

TABLE I.—*Virtual Resistance, &c., of Conductors with Alternate Currents.*

Diameter.		Area.		Increase over Ordinary Resistance.	Current at 450 amps. per sq. in.	Watts at 2,000 volts.	Watts at 100 volts.	∿ per second.
MM.	Inch.	Sq. mm.	Sq. in.					
10	·3937	78·54	·122	Less than $\frac{1}{100}$ %	55	110,000	5,500	80
15	·5905	176·7	·274	2½ %	133	266,000	13,300	
20	·7874	314·16	·487	8 %	220	440,000	22,000	
25	·9842	490·8	·760	17½ %	...	...	...	
40	1·575	1,256	1·95	68 %	...	...	...	
[100	3·937	7,854	12·17	3·8 times	...	...	...	
1,000	39·39	785,400	1,217	35 times	...	...	...	
9	·3543	63·62	·098	Less than $\frac{1}{100}$ %	45	90,000	4,500	100
13·4	·5280	141·3	·218	2½ %	98·5	197,000	9,850	
18	·7086	254·4	·394	8 %	178	356,000	17,800	
22·4	·8826	394	·611	17½ %	...	...	...	
7·75	·3013	47·2	·071	Less than $\frac{1}{100}$ %	32	64,000	3,200	133
11·61	·4570	106	·164	2½ %	74	148,000	7,400	
15·5	·6102	189	·292	8 %	131·4	263,000	13,140	
19·36	·7622	294	·456	17½ %	...	...	...	

It will be seen that for 100 ∿, with wires of 9 millimetres, or ·35in. diameter, the increase over the ordinary resistance is almost imperceptible ; for a diameter of 13·4 millimetres, or ·53in., it is only 2½ per cent. ; while what may be considered a practical limit is reached at 18 millimetres, or nearly ¾in. At greater diameters the increase is prohibitive, and multiple conductors, tubes, or strips must be used. Probably an increase of 8 or 10 per cent. will be considered quite permissible. It sounds a good deal, but it must be remembered that it is only 8 or 10 per cent. of the 1 or 2 per cent. loss for which primary conductors are usually calculated.

Looking at the limitations as regards output, it may be said that for primary distribution, even at no higher tension than 2,000 volts, the virtual resistance effect is, if not quite unimportant, at any rate not very serious. A current of about 200 amperes may be conveyed without the effect showing itself to any very objectionable extent. There may be differences of opinion on the subject, but most people will agree that 300,000 or 400,000 watts is quite as much as should be supplied through any single conductor. In most cases, even at ordinary tensions, subdivision of the primary will be necessary or advisable before such a power is reached. With still higher pressure, of course, enormous powers can be dealt with without exceeding the permissible size of solid conductors. It is to be observed that there is nothing in this virtual resistance effect to necessitate the reduction of current by the employment of very high pressures.

It is only with the low-tension secondary conductors that this effect becomes in any way serious. With 100 volts the maximum load at this density that can be put on a single solid or stranded conductor is about 13,000 watts for 133 ∿, 18,000 for 100 ∿, and 22,000 watts for 80 ∿, unless much more than the 8 to 10 per cent. increase can be endured. This only means in large distribution work a subdivision of the primary and secondary feeding points in accordance with this limitation. The inconvenience has only to be recognised to be avoided. Fortunately it is not one that with ordinary care is likely to lead to any practical inconvenience. It exists with alternate currents, but it is a matter that the transformer system renders it very easy to avoid. Transformers lend themselves to subdivision of work, and with subdivision this difficulty does not exist.

It may be worth noting, in connection with this part of the subject, that the improvement in alternators, and the great ease with which they and their circuits can be worked and controlled, may lead to some revival of the practice of supplying direct from low-tension alternators. If this is done for any but very small installations it is evident that special precautions must be observed to avoid the difficulties which have been referred to.

One other remark on this subject. Very large conductors are to be avoided in the transformers as well as outside of them. This is only mentioned on account of its bearing on transformers for any very low tension work, such as electric jointing or welding, where one or two turns of secondary conductor is often sufficient.*

4. *Transformers.*—There appears to be a general belief that a high periodicity is best for transformers, and that this gives the greatest output, or—what amounts to the same thing—that with the same output in the two cases a higher efficiency is obtained when the periodicity is high than when it is low. This supposed fact has often been stated.

Prof. Forbes—who has, I believe, given much attention to the theory of this very difficult subject—contributed a Paper last year,† consisting of a mathematical examination, which is summarised and concluded by a statement that the periodicity may be diminished without loss of efficiency if the iron be increased ; the corollaries being, of course, that the periodicity may be increased without loss of efficiency if the iron be reduced, and that with any given transformer an increased periodicity results in increased efficiency for the same output, or in greater output with the same efficiency.

Prof. Forbes confirmed this view recently, in the discussion on a Paper by Mr. Kapp before the Institution of Civil Engineers, by pointing out that one of the reasons why in America they used a high periodicity was that "they wanted to get the greatest output from their plant, and transformers had to be increased in size in order to give the same output if they lowered the number of alternations."‡ And in his recent Paper on "Central Stations" before this Institution,§ Prof. Forbes reiterated this. He states that the contrary is "opposed alike to experience and theory. Westinghouse knows this. I am imformed Mr. Farranti knows it, and Mr. Zipernowski has told me that he finds it so."

Mr. Kapp, who works at 80 ∿, does not go so far as Prof. Forbes, for he thinks that on account of viscous hysteresis there must be a limit beyond which an increase becomes disadvantageous. He wisely adds that it is not possible to determine this limit on theoretical grounds.

On the other hand, it has been said that it is not necessary to increase the size of transformers even for very low periodicities, because, when the number of cycles is small, it is possible to work at a higher magnetic density.

I venture to question the accuracy of both these extreme views.

So far as transformers are concerned, and speaking only from experience, I think that high and low periodicities are both wrong, and that a medium rate is right. For a given output and efficiency not only must transformers be made large for low rates, they must

* The following particulars refer to conductors for primary circuits working at 2,000 volts, and show the sizes for various numbers of lamps giving a loss of 1 per cent. per mile run.

Data for copper conductors working with 2,000 volts pressure at the primary terminals of the transformers.

Transformers taken at 95 per cent. efficiency.

To allow 1 per cent. loss of pressure per mile of conductor, the primary current density should be 450 amperes per square inch.

Conductor for any given number of 60-watt lamps.

Sectional area in square inches = number of lamps × ·00007
Weight per mile, in lbs. = „ „ × 1·44
Resistance per mile in ohms = 630 ÷ number of lamps.

The following conductors comply with the above rule, and none of them is affected by the virtual resistance effect :—

Number of Lamps.	B.W.G. No.	Diameter.	Sectional Area.	Weight per Mile.	Resistance per Mile.

Digitized by Google

also be made large for high rates ; but between the two there will be found a periodicity giving the smallest size of transformer, or the greatest output, or the highest efficiency.

Fig. 2 illustrates this. It shows the rise of temperature of one of my transformers working respectively at 75, at 100, and at 125 ∿ per second. The primary and secondary virtual potential differences were measurably the same in all three cases, and in each case the same load was used, consisting of a certain number of glow lamps. The test was continued each time long enough for the transformer to attain its maximum temperature. This was taken by a sensitive thermometer, the bulb of which was placed directly on the iron, and covered by a packing of cotton waste to ensure that, as far as possible, at least the actual temperature of the iron should be indicated. Another similar thermometer was placed a few feet away to show the temperature of the room (which was fairly constant at about 60°F.).

The curves give the actual increments of temperature, which may be taken as some sort of measure of the relative efficiency attained. With any given output the same rise of temperature is, of course, always obtained with the same efficiency, quite apart from how that efficiency is made up. It will be observed that the lowest temperature or the highest efficiency is obtained at 100 ∿ ; that the efficiency is lower at 125, and lowest at 75 ∿.

On these lines I may suggest a method of arriving at the efficiency of transformers, which, though lacking in directness, is simple, and requires only ordinary appliances and facilities.

First run the transformer for some time in the usual way on incandescence lamps, the output being measured. It is not necessary to make any measurements of the primary. By means of

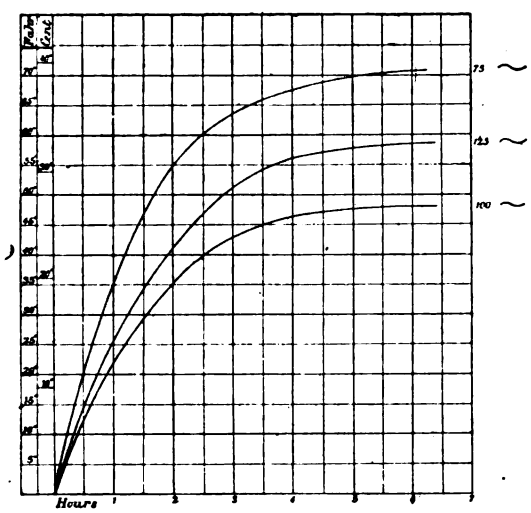

Fig. 2.—Rise of Temperature of Transformers at various Periodicities.

a thermometer find the rise of temperature of the transformer. Then, when the transformer has cooled down, send a continuous current through it, and measure the power in watts that raises the temperature of the whole transformer the same amount as when working with alternate currents. This takes some time to carry out, but it is accurate, and has the advantage that the lost power is measured in direct current quantities, about which there is no question ; while the power expended in the lamps, being in an inductionless circuit, is easily arrived at correctly. A wattmeter is the best instrument to use for the direct-current readings, as on account of the rise of resistance of the conductor (which is necessarily required to carry much more than the usual current), some adjustment is necessary in order to keep the power constant, and this adjustment is effected much more conveniently with a wattmeter in circuit than if an ammeter and a voltmeter are used.

5. *Lamps, &c.*—Under this head all apparatus for utilising or measuring alternate currents should be considered, so far as the action is affected by the periodicity. I must, however, confine myself to the lamps, which are the most important, and are the only apparatus as to which I can make any definite statements.

The Paper of Profs. Ayrton and Perry, read last year before the Physical Society,* showed that the efficiency of glow lamps is the same for both direct and alternating currents. The authors of that Paper did not directly allude to the question of relative efficiency with different periodicities, but they evidently had this point in their minds, as the periodicities used in the experiments appear to have been varied from 83 to 226 without showing any difference in efficiency. It may be taken, therefore, that no difference exists. Probably for very low periodicities this would not hold good, but for ordinary rates the question may be considered settled. At very low rates the temperature of the filament would follow to some extent the changes of the current, and would be affected both in life and in efficiency. I suppose that at ordinary rates there is no variation of temperature, the filament acting as a kind of thermal fly-wheel, maintaining its condition unchanged throughout the whole period. We all know for instance that, especially with low-resistance lamps, when the current is interrupted the time occupied in cooling down to blackness is quite appreciable. The periodicity at which the temperature begins to follow the variations of current is a point of some interest, and it is one that can be very easily investigated.

There is, as far as I am aware, no available evidence regarding the life of lamps with different rates, or even as to the relative life with direct and alternate currents. At one time it was considered that alternate currents would give better results than direct currents, because with the latter there was supposed to be some transference of the material of the filament in the direction of the current. Nothing has transpired to confirm or disprove this supposition, and, as the number of lamps now in use on each system is enormous, the very absence of evidence may be taken as affording a strong presumption in favour of the belief that the life of lamps is independent of whether the current is direct or alternating, and independent also of the periodicity, within practical limits.

Alternate-current arc lamps are not seriously affected by variations of periodicity within a fairly wide range. The feeding current of a parallel Brush alternate-current lamp remains sensibly constant between 75 and 125 ∿, but with the lower rate a slightly higher impedance or resistance is required to secure steadiness of the light.

Secondary E.M.F. Transformers.

The best potential difference to be used on transformer circuits has been a good deal discussed, especially with reference to the voltage of lamps. It is very desirable to arrive at some conclusions on this matter, not only as to glow lamps but as to the general question.

The balance of opinion—which is, however, not very decisive—appears to be in favour of using 50-volt rather than 100-volt lamps, so far as durability of the lamp is concerned. The stout low-tension filament should last longer than the finer one for high tension, because disintegration does not so soon reduce the cross-section to the breaking point. It is, however, not a question only of life, as the disintegration of the thick filament causes blackening of the globe ; and if it can be shown that this blackening, and the consequent lowering of the effective light, is more serious than in 100-volt lamps, then the advantage of slightly longer life will not of itself be sufficient to recommend 50-volt lamps in preference to others of higher voltage.

Of course the most serious objection to lowering the voltage is the increased cost of the secondary conductors. This is not important in small and very compact installations such as can be so readily supplied by transformers—for instance, in small shops and ordinary houses, where a separate transformer may be placed within a few yards of the lamps, and where the fall of potential is negligible ; but for larger work it is advisable to keep the potential difference high, as with direct currents, and for the additional reason that the use of very large alternate currents, with correspondingly large conductors, is accompanied by the inconveniences arising from the high virtual resistance already alluded to.

It is impossible, however, to choose an E.M.F. that will meet all requirements. For instance, high candle-power lamps are coming largely into use, and as this practice extends, higher E.M.F. will be demanded in order to keep down the diameter of the "stick."

But, on the other hand, lamps of small candle-power can be more easily made for low than for high voltage ; and as there is a growing tendency to use small candle-power lamps which in many situations give all the light that is required, this point should be kept in mind, especially as it is very probable that before long a demand will spring up for lamps of three or four candles. I know it will be said that it is easy to reduce the candle-power of ordinary lamps by inserting an impedance coil in the circuit. This is one of the many conveniences of transformer working, but it should not be resorted to for permanent purposes, as, however little power such a coil may absorb, lamps reduced in that way, being worked at less than their normal candle-power, are very inefficient.

Then there is another reason for sometimes preferring 50 volts to 100 volts that I should like to mention, and that is that alternate-current arc lamps do not require more than 50 volts terminal pressure. It may be expected that many such lamps will be used on transformers—for instance, at small business places, where perhaps the bulk of the lighting will be internal and by incandescent lamps, but where it will be convenient to have one or two arcs outside. We know that when arcs are used in parallel with incandescence lamps on direct-current circuits, it is necessary, in order to get

* *Jour.* Physical Society, Vol. IX., p. 208.

Digitized by Google

the best results, to have 12 to 15 volts drop of pressure in a fixed resistance in series with each arc. Thus has arisen the custom of using 65 volts for mixed arc and glow lamp circuits, where the potential difference at the arc lamp terminals is reduced to about 50 volts by the insertion of such a resistance, the incandescent lamps, however, being made to work at 65 volts.

This is a very wasteful arrangement, but, apart from its wastefulness, 65 volts is a very inconvenient pressure both from the manufacturer's and the consumer's point of view. It does not lend itself to combination as does a pressure of 50 volts. Dynamos, lamps, or transformers for 65 volts cannot be used in pairs on 100-volt circuits as can such apparatus for 50 volts. It is an irregular and inconvenient pressure that is demanded by the necessities of direct currents, but that I am glad to be able to say need not be imported into alternate-current work.

This very serious loss can be almost entirely avoided with alternate-current arcs, as the necessary steadying effect is readily obtained by the use of an impedance coil, absorbing much less power than does a resistance; and as such arcs require only 35 to 40 volts between the carbons, instead of 45 to 50 with direct currents, it is sufficient to provide 50 volts potential difference between the secondary conductors.

But it may be said that as impedance coils absorb little power the arc lamps may be put on 100-volt circuits in parallel. This may be done without much objection so far as the lamp and impedance coil are concerned, but there is the drawback that the "plant-efficiency" of the transformer will then be low.

The output of a transformer is limited partly by the size of the conductor. The actual output of a 100-volt transformer supplying arcs through impedance coils will not be much more than the product of the current × 50 volts, while for the same output in watts on glow lamps it would only have to yield about half the current. Therefore we see that, although not inefficient, the maximum allowable output of a 100-volt transformer on parallel arc lamps is only about one-half of its ordinary maximum output.

It will be said that two arcs may be run in series on the 100-volt secondary. This is true, but two arcs are not always wanted; and, further, the working of two arcs (which must for this purpose be shunt or differential instead of simply series-wound) in series on a constant potential difference is the least satisfactory way of arranging arcs, whether for direct or alternate current, as in this way they affect one another the most, having neither the margin of controlling power, by current, which is provided in the parallel constant potential difference arrangement, nor by E.M.F., as in the series constant-current arrangement. Then, again, lamps so connected must be extinguished together, as no cut-out or switch can be used unless it is made to insert a resistance or impedance to take the place of the extinguished lamp.

On the whole, therefore, it is preferable to have 50-volt secondaries where arcs are to be used, or to adopt the intermediate plan of connecting the middle of the 100-volt secondary to a third terminal, using a third wire for any arcs or 50-volt lamps that may be required. It may be worth while to point out that the use of a third wire on transformer circuits may lead to difficulty if not carefully considered. With a single transformer it is as easy to use three or any other number of terminals for the lamps as it is to do so on a set of accumulators, and to get any corresponding potential difference. The various sections of the secondary may be unequally loaded by this arrangement, but the primary responds as a whole to the demand made upon it. If, however, instead of a single transformer two transformers are used, with their primaries and secondaries respectively in series, then the use of the three-wire principle is only possible when it is applied to both the primary and secondary circuits, unless the load on each of the two secondaries is always to be alike and the same, in which case, as scarcely need be said, there is no particular advantage in using three wires. If the loads are not equal on the two, then the primary of the least loaded transformer acts as an impedance coil to the other primary, and all power of self-regulation is lost. One remedy for this is to apply the three-wire principle to the primary as well as to the secondary; but this is a serious matter, and one that could only be undertaken where the whole service demanded it. Another plan is to have two mains for the primary and three for the secondary, and to join the primaries parallel, the secondaries being in series with the third wire at the middle terminal.

In cases where arcs have not to be used, and in the absence of any very strong evidence of any difference of life in favour of 50-volt lamps, I think it is best to use 50 volts for small separate installations, and 100 volts for larger ones; but it is evident from what has been said that there are so many points to consider that it is quite impossible to give any definite negative or affirmative reply to the question, "What is the best secondary E.M.F. to use?" Each case, or at least each class of cases, must be settled on its merits. If for general convenience any particular pressure is selected, it is obvious that it will have about equally strong arguments for and against it.

Alternate-Current Arcs.

Reverting to this subject, it is to be regretted that very little appears to be commonly known about A.C. arcs. I trust that in the discussion of this Paper some information may be furnished with regard to them.

As to the regulating mechanism of lamps, although some difficulties were encountered in modifying the Brush arc lamp for this work, the result has been perfectly satisfactory; the feeding range is very small—quite as small as with direct currents, and with no greater loss of power in the lamp-box. Some trouble was experienced in getting rid of noise and vibration in the coils and mechanism, but this has been completely overcome, the lamp itself being quite silent. This is readily proved by connecting the carbon-holders by a flexible wire and adjusting the current to the normal value, when it is found that there is no noise. An A.C. arc is not silent, as is well known, a distinct hum being set up, by which it is quite possible to ascertain the periodicity.

This humming noise, which can scarcely be expected to be overcome, renders A.C. arcs unsuited for general use indoors; but for outside illumination, and for such places as railway stations, they will certainly find a very extensive application.

I venture to think that the opinion so often expressed that A.C. arcs give much less light than those supplied with direct current is founded on a misunderstanding of the proper conditions. It is quite true that if two arcs are compared, supplied with the same amount of current, the direct-current lamp will prove the better one. This, I think, is because the basis of comparison is not right. In many cases the A.C. arcs are more efficient. They should be judged by the energy, and not only by the current. I have mentioned that an A.C. arc requires only 35 to 40 volts potential difference between the carbons, while a direct-current arc requires 45 to 50 volts. The mean may be taken at 37·5 volts and 47·5 volts respectively, and to expend the same energy in the two cases the current should therefore be in the inverse ratio of these values. Thus, an A.C. arc to give the same light and to absorb the same power as a 10-ampere direct-current arc should be made for 12·6 amperes.

In one respect A.C. arcs are inferior, and that is their power of directing the light downwards. They have no "crater," and therefore do not send the light down as do direct-current arcs. On this account it is advisable to use reflectors above them, unless they are suspended below and near a good reflecting ceiling or roof.

But even this drawback is counteracted in parallel work by their greater efficiency. On a 65-volt circuit with direct currents, as I mention elsewhere, there is a waste of 100 to 150 watts with a 10-ampere arc, and in the same proportion with other currents. This is a very serious proportion of the whole power, and it is only allowable to waste it because, as a light producer, the arc is so much more efficient than the incandescent lamp. Nevertheless, any means of avoiding the loss is to be welcomed, and with A.C. arcs it may be greatly reduced by the use of impedance coils, which, if properly designed, waste very little power, and have all the steadying effect of resistances.

(To be continued.)

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 18, 1889.

The final steps of the consolidation of the Edison electric light interests are now being taken, and an important circular has been issued by Mr. J. B. Williams, who at the present time is the President of the Edison General Electric Company. This Corporation acquires the stock of the Edison Electric Light Company, the Edison Machine Works, the Edison Lamp Company, and Bergman and Company, and it is also stated that arrangements are being made to acquire stock in the Sprague Company, should it be found desirable to do so. The Edison General Electric Company, whose incorporation under the laws of this State I noted recently, has a capital stock of $12,000,000. It is stated that the purchase of the various interests is equal to a capital sum on which the net earnings of the three manufacturing companies, as obtained from their books, show a net income of nearly 15 per cent. during the year ended November 1, 1888. In order to give greater security and stability to the project, dividends will only be paid at present on a part of the stock issued to the shareholders of the old concern, the dividends on the remainder being postponed until such time as at least 8 per cent. has been earned. Some

Digitized by Google

idea of the basis of the deal may be formed from the statement that the shareholders of the Edison Electric Light Company will receive for each old share of $100 in the Electric Light Company $175 in the stock of the General Company, carrying full rights as to dividends, and $91 two-thirds in trust certificates of stock on which the dividends are deferred. Thus each of the stockholders will receive $266 two-thirds, making a total of $4,000,000 for the entire $1,500,000 of the old company. It is further stated, with regard to the General Company, that $2,666,650 of its stock will remain unissued for the present, available for future use. Hence it would appear that the Edison business as a going concern has been secured for $9,333,350. While details are not published as to the ownership of the stock of the manufacturing companies, it is generally understood that Mr. Edison has had a large interest in them, such, for example, as the Machine Works and the Lamp Company, both of which have, if I am not mistaken, been an ordinary co-partnership in the hands of five or six people. As I have before mentioned once or twice, this whole scheme of reorganisation has been carried through by Mr. Henry Villard, who in due course will become the president of the General Company, the present president, Mr. Williams, being his representative. It is also stated that the vice-president in the company will be Mr. J. H. Herrick, a well-known New York citizen.

Curiosity is naturally aroused as to what will become of the organisations which thus pass under the control of the General Company, and it may be stated at once that the intention for the present is to continue them as separate companies or establishments, each constituting a department of the business. While there will probably not be much change among the officers, a certain amount is to be looked for. It is very likely, for example, that Mr. E. H. Johnson, relieving himself of the responsibilities of active management of the whole of the Edison lighting business, will devote his attention to the interests of the Sprague Company, of which he is president, and whose business is growing so rapidly. It will be noticed that the Edison General Electric Company is likely to take a direct interest in the Sprague Company, and such a help will probably not be unwelcome, for the chief trouble nowadays is not to get the business, but to handle it when obtained. These new street railway contracts, involving a dozen miles of track and some 30 or 40 cars, with a big power station, require plenty of money for their execution, and thus involve heavy financing.

Quite a sensation has been caused in electrical circles here by the announcement that Mr. Edison has brought suit against two old and confidential associates for money which they are alleged to have received as his agents, but which, it is said, they have failed to pay over to him, or in regard to which he had been kept in ignorance. To summarise as briefly as possible the story told by Mr. Edison, it would appear that whilst he received only $500,000 for all his interest in the phonograph, his two confidential representatives received no less than $250,000, although his belief was that they were receiving but $75,000. He states that had he known that a secret agreement was to be carried out he would not have sold the stock of the Edison Phonograph Company at the price he did, but would have asked a higher amount of money for it. It might be added that of the $500,000 paid for the phonograph Mr. Edison did not receive the whole sum, as in accordance with his usual custom he distributed 1,750 shares of stock in the Phonograph Company among his assistants. Altogether it will be seen this is a pretty kettle of fish, and if report be true it does not go quite to the bottom of all the troubles concerning the development of the phonograph business. The gentlemen in question both deny very emphatically that they have in any way taken advantage of Mr. Edison while acting as his trusted and confidential agents, and that so far from being *beneficiaires* of Mr. Edison their relations with the distinguished electrician have resulted in financial loss to both.

Your paper, containing a keen editorial on the subway situation in this city, and discussing explosions, came to hand yesterday, and, as if to emphasise some of its remarks, we had another subway blow-up last night in Union-square, not far from the scene of the other explosion. Fortunately it occurred about 10:30 p.m., when there were very few vehicles or pedestrians in the vicinity, but it tore up 30 feet of the street, and the noise was heard for several blocks. This, of course, brings the matter to public attention again, and we are still without any adequate explanation of the trouble. At the present time there is not so much activity in pole cutting, but there is considerable dispute as to who shall pay for the work that has been done—whether it shall be the city or whether it shall be the companies whose property has thus been taken from them and destroyed. It is interesting to note that while this pole-cutting campaign has been going on the belief in the sincerity and public spirit of the Mayor has been considerably shaken, more, perhaps, by inference than by any direct proof of iniquity; in other words, he has had to make several appointments in city departments, and his selections have been so peculiarly bad, and are so suggestive of jobbery and truckling, that people are beginning to question whether the Mayor is such a remarkably virtuous and public-spirited individual after all.

Last week I mentioned the fact that Mr. Harold P. Brown had been surreptitiously purchasing Westinghouse alternating apparatus for the State, for the purpose of electrical execution. At that time there was nobody with sentence of death upon whom the new punishment could be inflicted, but since then a murderer has been condemned at Buffalo and the Judge has ordered that his execution shall take place by means of electricity on the 24th of next month at the Auburn prison. It will be remembered that the law establishing electrical execution was also very severe in it provisions against the publication of any details of the carrying out of the sentence, this restriction being directed against the sensationalism that often attends an execution and which places criminals before the lower members of the community almost in the light of heroes; but, as may be readily imagined, with a new method of execution to be tried, and with the invincible determination of the American newspapers to get the news, and all of it, it will be rather hard for the authorities to carry out the rule; in fact, it would be anything but wise at the outset to thrown any special mystery or obscurity around the new means of execution, for in the absence of definite details extraordinary exaggerations would get afloat, and the public mind would be worked up, and more harm than good would result. While very few electricians are found here in favour of using the electric current for capital purposes, we are all watching the results of this first use of it in an execution with considerable interest, and on the part of the public there is naturally a great deal of curiosity.

CORRESPONDENCE.

THUNDERSTORMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: From September, 1888, to March, 1889, I was staying in the plains of the Argentine Republic, not very far from Rosario, in the Province of Santa Fé. The weather was very exceptional, no less than 27 thunderstorms passing over the estancia where we lived in the period named. I was able, therefore, to make a few notes of a general nature on this subject.

(1.) *Is there "Sheet" Lightning?*—By climbing a ladder on to the roof of a large barn, I was able to watch the approach of each thunderstorm, the more readily as the plains were perfectly flat and devoid of trees. When the storm was very distant I noticed merely a silent lighting-up of the horizon—exactly like what is so often called "sheet" lightning in England. As it came nearer I could see part of or the whole of a vivid spark, as well as the lighting-up of the clouds, but still there was no sound. It was after the sparks had been in sight some time, and when the storm had come still nearer, that I could hear thunder following the spark.

After observing all these storms, and others that passed by us but were felt elsewhere, I came to the conclusion that I had never seen any "summer" or "sheet" lightning in England which did not resemble in every respect the appearance pre-

Digitized by Google

sented by a *bonâ fide* "flash" occurring either very far off or behind very thick clouds; or, in other words, I came to the conclusion that I had no reason to assume that there is a "silent lightning discharge," the [noisy] spark discharge giving, under suitable conditions, all the appearances that had ever come under my observation.

(2.) *Discharges not Usually to Earth* (?).—During these thunderstorms the lightning would be for some hours almost continuous. Thus, one storm, January 6 and January 7, lasted nearly twelve hours. During the whole time the lightning was constant, and for some hours it was so continuous that one was able to go about in the yard, draw water from the well, fill vessels with water, and perform other operations requiring fairly continuous light; in fact, but for the trying effect on the eyes, I could have done some reading by the light.

Now there were 45 square miles of plain belonging to the estancia, and in all this space there were no trees, the most prominent objects being cattle and horses. There were round this estate posts of wood with wire.

During the whole 27 thunderstorms there was not one single case of an animal being struck, nor any sign of any single post having suffered. [Had the posts been of iron this would have been natural; but they were of wood.] Nor, as far as we ascertained, had any of our neighbours suffered from lightning.

I may add that my brother had lived for many years where there was no wire fencing, and that there, as also when within a fence, it was a rare occurrence for any animal to be struck.

The conclusion I was led towards was that nearly all the discharges were between cloud and cloud, not between cloud and earth. In a 12 hours' storm, for example, the discharges that took place somewhere over the estate were probably to be numbered in hundreds at least, so continuous was the flashing. If this were mainly the re-establishment of electrical equilibrium between earth and clouds, could the cattle on a flat, treeless plain have escaped?

Further, as far as one could judge by watching, the sparks did seem, as a rule, to be between one part of the sky and another. In all the 27 storms I observed this.

(3.) *Source of Electrical Disturbance* (?).—As far, then, as I could see, the discharges took place to a large extent up in the air between different clouds. The incessant flashing, moreover, seemed to point to a continuous exciting cause. Is it possible that it was the meeting of two currents of air that resulted both in the condensation shown in the heavy clouds and also in the electrical disturbance shown in the continuous flashes of lightning?

It seemed to be a general rule that a thunderstorm came up *against the* [*lower*] *wind*. Does not this suggest friction between two currents of air, a higher and a lower? Further, storms appeared to come back again after having passed, which again suggests irregularities in the wind currents.

It is of course an undoubted fact that in thunderstorms we have some lightning flashing to [or from] the earth. But I cannot help thinking that in these storms of the plains, at any rate, nearly all the discharges were from cloud to cloud.

Cheltenham, May 20, 1889. W. LARDEN.

MR. ATKINSON'S WORK ON "ELECTRIC LIGHTING."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has just been called to a notice served on Emmot and Co., of Manchester, by E. and F. N. Spon, of London, in regard to the sale of my work on electric lighting, claiming that the book "is an infringement upon the copyright of Prof. S. P. Thompson's "Dynamo-Electric Machinery," and that Prof. Thompson will take action in the matter if the sale is continued."

This is the same threat in more definite form made last fall when the book first appeared, to which I replied in the London *Electrician* of December 28, 1888, and the *New York Electrical Engineer* of January, 1889, stating fully and explicitly that while I had consulted various authors in the preparation of my book, and obtained information from every available source, no one could show a line improperly appropriated from any other writer.

I find nothing now to add to that communication, which covered all the details in regard to the preparation of the work which could be of any interest or importance. More than four months have elapsed since it appeared, and no one, so far as I am aware, has attempted to reply.

Among the various criticisms which have appeared it is strange that no discovery has been made of the plagiarism alleged by Prof. Thompson and his publishers. The fourth edition is now before the public, and I will kindly thank Prof. Thompson to point out anything in it wrongfully appropriated from any of his works.—Yours, &c., PHILIP ATKINSON,

May 10, 1889. 168, Randolph-street, Chicago, Ill., U.S.A.

A SEVERE TEST OF THE HOUSE-TO-HOUSE UNDERGROUND MAINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You may be interested to hear that at 3 a.m. last Sunday the West Middlesex Waterworks Company's main pipe, 5in. in diameter, at a pressure of 125lb., burst in Barkstone-gardens. The quantity of water that escaped was so great that it inundated the road and caused the ground to sink considerably. Their pipe was laid 3ft. 6in. below the road level, and our electric light supply mains were above their pipe about 2ft. 6in. One of our road boxes was exactly over the spot where the pipe burst, and as a large quantity of soil was washed away, our box was lowered a matter of about 18in. The pipes followed the box, giving only at the cork joints, without a single breakage. The pipes filled with water, which travelled along and trickled into the basements of one of the houses we are lighting. I am pleased, however, to advise you that the cable continued to run the lights satisfactorily.

I consider this a very severe test to any underground system of electric lighting; indeed, a lamp-post only ten yards distant fell down under the exceptional sinking of the, ground, and twelve cartloads of gravel had to be put on in order to bring the road to its proper level again. Our mains were raised as before without the slightest injury to the working within twenty-four hours of our hearing of the accident that had occurred.—Yours, &c., CHARLES J. HALL.

Kensington, May 28th.

P.S.—You are doubtless aware that under the system advocated by other companies in Kensington a breakdown under such circumstances would have been inevitable.

4,800. LAKE (Brooks). Electric conductors. (Price 6d.)

5,095. HASLAM. Secondary batteries. (Price 6d.)

5,612. LAKE (Rice). Distributing electric currents. (Price 8d.)

COMPANIES' MEETINGS & REPORTS.

Submarine Cables Trust.

The eighteenth ordinary annual meeting of the certificate holders in the Submarine Cables Trust was held at the offices of the Trust, Winchester House, Old Broad-street, on Friday, the 24th inst., Sir John Pender presiding.

The SECRETARY (Mr. Lewis Wells) having read the notice calling the meeting,

The CHAIRMAN said: Our revenue for the past financial year amounted to £19,118, as compared with £17,948 in 1888. As mentioned at the last meeting, the certificate holders for the two previous years received payment of their coupons at the rate of 4½ per cent. For the year ending April, 1889, the accounts of which are now submitted, they have had a return of 5⅝ per cent., and if we should not be disappointed in our estimate of revenue for the current year we hope to pay the full 6 per cent. The coupons are, as you know, cumulative, and we are now one coupon in arrear. We can only clear this off when our revenue exceeds the amount required to cover expenses and the two half-yearly coupons, together 6 per cent. For the past year our investment in Anglo-American stock has yielded us a dividend equal to £2. 8s. 10d. per cent., as against £2. 1s. 4d. per cent. in 1888, and if the Company should pay only 2½ per cent. for 1889, this will give the Trust a return of £3. 17s. on its investment. Having so large an interest in the Anglo-American stock, it is satisfactory to remark the improvement in the position of the Company. It is hoped that the trans-Atlantic traffic will grow at the 1s. rate, so as to render unnecessary any increase of tariff. Our other investments call for no special observations. We expect to be in a position to make a payment of £2. 10s. on account of the outstanding coupon on October 15th, and to pay the balance of 10s. a month later. We can only make these payments as the money comes in from our investments. I can only say that, being very intimately connected with the various telegraph companies, our prospects at the present moment are very satisfactory indeed. With improving trade there is generally an improvement in telegraphic traffic, and especially I think I may say that there is a marked advance in the traffic in those companies in which this Trust is interested. He concluded by formally moving the adoption of the report and accounts.

The MARQUIS OF TWEEDDALE seconded the resolution, which was unanimously adopted.

Mr. LAMONT moved, and Mr. PAYNE seconded, the reappointment of the auditors, Messrs. John G. Griffiths and John Gane.

The motion having been agreed to, a vote of thanks was passed to the Chairman, which concluded the business.

The Submarine Telegraph Company.

An extraordinary general meeting of this Company was held on Tuesday, at the offices, 2, Throgmorton-avenue, London-wall, under the presidency of Sir J. Goldsmid, Bart., M.P.

The SECRETARY (Mr. S. M. Clare) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, you will be surprised that we have called you together again, but the reason is very simple. You are aware that we have been a chartered company, and the proceedings for a chartered company are not exactly the same as for a company which is established under the ordinary company law. We thought if we passed the resolution which is suitable for a chartered company to pass, appointing liquidators and authorising a liquidation, that that would be sufficient, but as we were also registered under the Companies' Clauses Act the solicitor to the Post Office has been of opinion that it was desirable that the resolution should be passed under the Companies' Clauses Act in addition to the resolution which we passed as a chartered company. Consequently we have called you together to-day, and we shall have to call you together again, to confirm the resolution I am about to submit to you. The object of the present meeting is therefore very simple, and Mr. Campbell, our solicitor, has put it in legal form. Perhaps you would like me to read it to you. It is as follows:—

"The Submarine Telegraph Company between Great Britain and the Continent of Europe was incorporated by Royal Charter, with a deed of settlement (the charter is still in force). The Company was also registered (some years ago) under the Joint-Stock Companies' Act, but without Articles of Association, and under the Act the deed of settlement became the Articles of Association. The deed of settlement provides a certain mode of proceeding for winding up the Company, and in conformity with this resolutions were passed on the 25th day of March, 1889, to wind up and appointing Sir Julian Goldsmid, Mr. Brand, and Mr. Clare liquidators, and these resolutions were registered at Somerset House. The Post Office made a requisition that the winding up and the appointment of liquidators should be in conformity with the winding specialup Act, which requires a resolution to be passed by two meetings for winding up under the Act. The Company are advised that the resolutions passed in conformity with the deed of settlement are sufficient. The only mode of settling the question would be by a special case and argument before the Court, which would take much time and incur much expense. It was therefore thought advisable to have resolutions passed for the winding up in conformity with the Act, which is the reason for calling the present meeting, so that the resolutions having been passed in both forms all possible objections will be thus removed."

We shall be abundantly authorised, both as a chartered company and as a company registered under the Companies' Clauses Act, to wind up, and consequently the resolution I shall propose will be this:—

"That the Company be wound up voluntarily under the Companies' Acts' 1862 and 1867, and that Sir Julian Goldsmid, Bart., M.P. (the Chairman of the Company), the Hon. Henry Robert Brand (one of the Directors), and Mr. Stephen M'Donnell Clare (the Secretary), be and they are hereby appointed liquidators for the purposes of such winding up."

If Mr. Ponsonby will second that—

The Hon. ASHLEY PONSONBY: I will do so.

The CHAIRMAN; I think that will put you in possession of the facts of the case. I do not know that you will expect me to give you much additional information; but I think I may say that we are proceeding satisfactorily with the liquidation. As you have seen by the papers, we have arranged with the Government for the sale at a price—an inadequate price—of the cables; and we have arranged also for the sale of this house,

Digitized by Google

the steamer, and, in fact, for the sale of all the property we had to dispose of. The Déolen cable, which belonged jointly to us and the Paris and New York Company, will in future belong absolutely to that Company, they paying us half-price, as was originally arranged in the agreement which we entered into with them. The only thing, practically, which we have to settle now is as to what is to be done with the Salcombe cable. That is a matter that will require still further negotiation and consideration, and I am not able to give you any information with respect to it. I have every hope in the course of a fortnight, or at the outside three weeks, that we shall return a very substantial part of the capital to the shareholders, and we hope that in the course of three months the liquidation will be completed. It is not possible for me to say at present what the exact amount will be, but we trust the shareholders will receive more than the capital of the Company ; and in the painful and trying circumstances in which we are liquidating I think that on the whole that is satisfactory. You may probably have seen the very hot discussion which took place in the House of Commons as to the price the Government pay us and the amount they have awarded as compensation to our *employés* whom they do not take over. I do not think that it is very desirable that I should discuss the proceedings in the House of Commons—first, because I am a member of that House, and secondly, because the vote is to be submitted to the full House on the report, and anything we might say here might interfere with that discussion. I think it is undesirable to say very much about it. It is the desire of the liquidators to proceed as rapidly as possible with the liquidation, and to return as much as they can to the shareholders. He then put the resolution to the meeting in the usual manner, and having declared it carried unanimously, stated that it might be convenient if he informed them that the meeting to confirm the resolution would be held on Wednesday, June 19th. Continuing, he said : In my opinion it is not necessary for us to pass the resolutions now which were passed at the last meeting, though we stated in the notice calling you together that we should do so. I do not think it is necessary to pass them for the reason that practically we have done everything. We have completed everything that was proposed in those resolutions except in regard to the Salcombe cable. It seems to me that under the ordinary powers of liquidators it is a part of their duty to sell and dispose of what property of the Company may be left. I therefore do not think it is necessary to pass all the resolutions in the notice of the meeting, but it may be advisable to pass the following one :—

"*That the liquidators be empowered to negotiate and sell, at a price to be fixed by valuation, or otherwise, the Salcombe and Déolen cables belonging partly to this Company and partly to the Société Carmichael et Cie.*"

The Hon. ASHLEY PONSONBY seconded the motion, which was unanimously agreed to.

At the suggestion of Mr. RUSSELL GRIFFITHS,

The CHAIRMAN afterwards submitted the two resolutions passed at the last meeting, empowering the liquidators to negotiate and sell at a price to be fixed by valuation or otherwise with the respective Governments any property belonging to the Company and the Société Carmichael et Cie., and authorising the liquidators to supplement the money which the Government has agreed to pay to the *employés* in England of the companies not taken into the service of the Government by a further sum not exceeding £500. These resolutions were also agreed to.

The CHAIRMAN : We have now proposed all the resolutions except the one as to authorising the Government to work the cables from the 1st of April. As they have been worked by them from the 1st of April I think it is unnecessary now for us to authorise them to do so (laughter).

In the course of a discussion which took place,

Mr. R. GRIFFITHS, in view of the Postmaster-General's recent remark in the House of Commons that the Company had been dealt with fairly and equitably, thought the shareholders should, as a body, express their opinion that the way in which the Company's property had been acquired by the Government amounted to a confiscatory act. The English Government, he added, had proposed confiscation to the French Government, who had been perfectly willing to assist the Company, but who, to protect their own nation, had been obliged to follow the lead of the English Government.

Mr. KING protested against the way in which the Company had been left to supplement the amount which the Government had agreed to award to *employés* not taken into their service. As to the terms on which the Company's property had been taken over by the Government, the Postmaster-General had admitted that, even in these days when there was competition, it would cost them £120,000 to lay new cables. It was, therefore, an act of injustice to the Company, the pioneer of submarine telegraphy, to require them to take a paltry sum of £40,000 or £50,000 for cables which, though not new, did their work perfectly well, and which would continue to work admirably. If the Government had given them £120,000 for the cables he would contend that they ought to have given more, as the cables had cost the Company more ; but the shareholders would have had less cause to complain had the amount in question been given them.

Mr. PAWLE said that the capital expenditure of the Company had been £331,000, and they would get back in round figures about £100,000.

The CHAIRMAN : I mentioned to the shareholders just now that we should repay them the whole of the capital, with probably some addition.

Mr. PAWLE : That is all very well, but we have a reserve fund.

The CHAIRMAN : That is included.

Mr. PAWLE inquired what had become of the capital ; how had it been expended ? Although they had spent the amount he had stated, and the auditors had said that everything was in perfect order, they were now to receive about £100,000, and he would like to know how the other £200,000 was to be accounted for.

The CHAIRMAN : With some of the remarks that have been made I can agree. I should agree that we are getting a very poor price for the property ; but I should not agree that the Government ought to pay us the price of new cables for old ones. It must be remembered also that when we laid our cables, cables cost a vast deal more than they do now, and it should further be remembered that one of our cables became an utter loss. Some of the remarks made would appear to hold me responsible because we did not get the value of the capital expended. The money has been honestly spent and certified by the accountants from time to time. It is unfortunate that our property does not represent the amount of value it originally held ; but it is fortunate that the Directors and the shareholders laid by a sufficient reserve fund, so that through that reserve fund and the amount we get for our cable, steamer, house, and other property, we shall get back our original capital with some small addition. Those who paid a high premium for their shares will not receive back that high premium ; but many who paid a high premium for their shares have been receiving high dividends, and if they were wise (as I am sure all our shareholders are) they probably put by a considerable proportion of their dividends as a sinking fund for their capital. Therefore, though I agree that we have not been handsomely treated, I can assure you that we have done our best to obtain the highest possible price for the Company. I have never gone through so much anxiety and given so much time to anything as to this matter, in the hope of obtaining reasonable terms for the shareholders. If I have not got all I hoped it was not because my colleagues and myself have not done our best. We must accept the position, which is disagreeable, but which might have been worse had not the shareholders and the Directors been a little provident.

The proceedings then terminated.

The Cuba Submarine Telegraph Company (Limited).

An extraordinary general meeting of the shareholders was held at the offices, 58, Old Broad-street, on Wednesday, A. F. Low, Esq., in the chair.

Mr. JAMES SCOTT, the secretary, read the notice, which stated that the meeting had been convened for the purpose of electing an auditor or auditors in the room of Mr. Thomas Greenwood, who has been appointed a Director to fill the vacancy caused by the death of Mr. Joaquin de Mancha.

The CHAIRMAN said : Before proceeding to the business of the meeting, gentlemen, I wish to give expression to the regret we feel at the loss of our late esteemed Chairman. We had the benefit of his experience during the fifteen years that he was a Director of the Company, and I am sure that during all that time nobody could have been more devoted to the discharge of his duties than he was. He was also a kind and genial friend and colleague, so that we have great reason to regret his loss. As the Board consisted of the minimum number of Directors required by the Articles of Association it devolved upon us to fill up the vacancy without loss of time, and we unanimously chose Mr. Greenwood, who has acquired a thorough knowledge of the business, and is otherwise highly qualified for the post. I have had the pleasure of Mr. Greenwood's personal acquaintance for many years, and I am sure that your interests will not lose anything by his appointment, which I hope you will cordially approve of. With these remarks, gentlemen, I now call upon you to elect an auditor in place of Mr. Greenwood.

Mr. SAVILE : Sir, I have great pleasure in proposing Messrs. Gane and Jackson, Chartered Accountants, of Coleman-street, as auditors of the Company. I have known them for many years, and I know that they are well acquainted with telegraph companies' accounts, and are quite capable and very desirable persons to act as auditors of this Company,

Mr. W. E. L. HOOPER seconded the proposition.

Mr. GRIFFITH : Are they shareholders in this Company ?

The CHAIRMAN : I believe they are not.

Mr. GRIFFITH thereupon offered himself to fill the vacancy, and in doing so referred to his long connection with the Company, and at some length detailed his qualifications for the post of auditor.

Mr. COCHRAN pointed out that nothing was said as to what the remuneration was to be.

The SECRETARY replied that whoever might be appointed would take the place of the auditor who was appointed for the current year, so that the usual fee of 20 guineas would stand.

After some discussion of a somewhat personal kind,

Mr. ROGERS proposed the election of Mr. W. Griffith as auditor.

Mr. FORSHAW seconded this proposition.

Upon being submitted to the meeting the vote was in favour of Messrs. Gane and Jackson.

Mr. GRIFFITH then said he was willing to serve as a second auditor in conjunction with Messrs. Gane and Jackson.

Mr. BOVILL proposed that Mr. Griffith should be so elected, and Mr. Rogers seconded the proposition.

The CHAIRMAN pointed out that for eighteen years they had never had more than one auditor, which was quite sufficient for the duty to be performed. The Company was only a small one, and it seemed unnecessary to add to the expenses by appointing a second auditor when a firm of accountants of high standing had been elected.

Mr. GRIFFITH said he would be content to divide the fee with Messrs. Gane and Jackson, so that the expenses would not be increased, or if the shareholders desired it he would do the work for nothing.

Mr. SAVILE, however, expressed his belief that Messrs. Gane and Jackson would not care to divide the small fee of 20 guineas with another auditor.

It was suggested that the Chairman should first take the sense of the meeting as to whether or not an additional auditor should be appointed. This was done, with the result that the majority decided against making any change.

Digitized by Google

Mr. BOVILL moved that a vote of condolence should be passed to the widow and family of Mr. Joaquin de Mancha, the late Chairman of the Company.

Mr. COCHRAN seconded the motion, and it was carried unanimously.

A vote of thanks having been passed to the Chairman, the meeting closed.

Consolidated Telephone Construction and Maintenance Company (Limited).

The eighth annual general meeting of the shareholders in this Company was held to-day at the Cannon-street Hotel, under the presidency of Mr. C. L. W. Fitzgerald.

The SECRETARY (Mr. Charles Curtoys) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Ladies and gentlemen, it is with very great satisfaction that I address you to-day. It will be in your recollection that last year, in February, the Board terminated the contract for the manufacture of telephones which had been running with the American Telephone Company for some four years. We did not do so very badly under the contract, but I have, I think, to congratulate the shareholders on the fact that we have done a very great deal better this year. Later on I will tell you how much better, but I think I must say that the reason no doubt that we have done better is that we have looked into the question of manufacture more closely than when we were dealing with a contractor who simply sold us the instruments at a fixed price, and which we sold again. Leaving the figures to the last, I will deal with the report as it is laid before the shareholders. The profit you will see for the year, with the balance which we brought forward, amounts to no less than £13,286 for disposal, after making provision for doubtful debts. The Board propose to deal with this sum by paying a dividend at the rate of 7 per cent. for the half-year—making, with the interim dividend paid in November, 6 per cent. for the year—and writing off £520 for depreciation of plant, machinery, and furniture, and the sum of £2,000 off goodwill and patent rights, leaving a balance of £1,558 to carry forward. The action in Belgium is still dragging along, I am afraid I must say. When once one gets into law it is a very slow matter, but I can inform the shareholders that so far everything has gone in our favour. That, I think, is a great point, and we have now reached the stage when the question is to be put into the hands of experts to decide whether any infringement of our instrument has taken place or not. Of course, in my own mind I have not the shadow of a doubt that it has, but as we are dealing with a foreign Court it is not possible for us to say what the issue will be. We must, however, hope that it will be a favourable one. I now come to the question of the factory. I think I never was more pleased with the way things are going on at the factory than I am at the present moment. I find that everything goes on smoothly. I have not said previously very much about what we have been doing at the factory, but you must not imagine that we are standing still there. On the contrary we are making improvements—I may say immense improvements—in the instrument we are turning out; and we are also making great improvement in our machinery in the way of making parts of the instruments with labour-saving machinery—a proceeding which saves very considerably in the expenses of manufacturing. It is very gratifying to us to find that we are enabled to do that, and that our profit from the manufactory has been £4,000 more than it was in the previous year. In other words, last year we had a profit of £5,773, whereas this year we have a profit of £9,784. I think that it is very satisfactory to us to see that we have made nearly double the profit of the previous year, and I only hope that in the next year the profit will be trebled. There is really very little for me to say to you about the figures. I think this balance-sheet may be said to be a fairly intelligible one. You will see that we have received in interest from various subcompanies, dividends on shares, &c., £2,371, and that we have received £3,044 from the liquidators of the River Plate Telephone Company. We have done all that we can to keep down the expenditure, and I think I may say that we have very fairly succeeded. Considering that the profit shows so large an increase, I do not think the increase of expenditure has been so much. In the first item at least the increase is only £60. I think I need say very little except in so far as our plant and machinery are concerned. They are all in perfect working order, and we have reduced the value in the balance-sheet by a very considerable a mount. The stock of instruments has increased a little, but that is very natural with our doing a larger business. The item last year was £4,719, and it is now £6,453. The amount owing to us, it is rather gratifying to find by the balance-sheet, is £6,381, against £8,072 last year, while we owe, on the other hand, only £1,459, as against £2,025 last year. I think those figures ought to be considered satisfactory by everyone. As to the question of the relationship between the United Telephone Company and this Company, I am happy to state that it is very cordial indeed; in fact, there is no doubt about it that we have had a great deal more business from the United Company, and I am gratified to be able to state that it seems to me likely to increase. We now have a very considerable number of orders on hand to execute, and as far as I can judge, looking around England, I think the business is likely to increase very considerably. You see an item in the revenue account, "expenses in connection with the Lisbon Exhibition." That is a very small item—only £33. We exhibited some instruments there, and only this morning did we receive a telegram from Lisbon from the managing director of the Anglo-Portuguese Telephone Company, stating, "Have received flattering letter regarding instruments exhibited by Consolidated Company from the committee of the Lisbon National Exhibition. Being a foreign exhibit, medal could not be awarded." In other words, as we were foreigners they could not give us an award, but they gave us great praise for the instruments we sent to them. Now, gentlemen, I come to the subsidiary companies. I think it is most gratifying to find that year after year (this is now the fifth year) we are going on seeing an increase in the rental of those companies. This year there has been an increase of no less than 613 in the number of subscribers, while the increase in the rental has been £3,410. It is in connection with these subcompanies that the Directors have offered to the shareholders—or will offer to them—the 15,000 Preference shares out of the 75,000 which are to be created. I may tell you that in 1884 the income from those companies amounted to only £10,000, and that £10,000 was practically absorbed in working expenses. The gross annual income from those companies has now reached a sum of no less than £26,500, and their net income was for the past year £11,050. From that sum we have to deduct the debenture interest and the preference interest of those companies, but after that there is left a net balance of earnings by those companies of £7,200. At present the whole of these earnings are expended in construction. You will readily understand that to put up a telephone to earn an annual subscription costs a considerable sum of money, and as we find that no sooner is one man supplied than another wants to have similar advantages, the result is that all our net profit is absorbed in putting people on the telephone as fast as ever we can. It is for that reason that we have proposed to issue these Preference shares. The idea is this: We issue 15,000 Preference shares to the Consolidated shareholders, and we hand on the money to the subsidiary companies, taking from them securities which will pay us 6 per cent. or more, thus bringing us back the money which we should have to pay on our own Preferences. By doing that we shall give these companies capital to enable them to free the revenue which they get every year, and which keeps on increasing, and with that revenue free they will be enabled to pay us dividends. It appears to me that the proposal is of the very greatest advantage to the shareholders of these companies. I have always told you that I looked for very great results from the subsidiary companies paying us dividends. You see we receive already £2,700 from them. Of course it is only an estimate, but I estimate if we carry out this issue of Preference shares that we shall get, to begin with, £3,000 more, and that sum will go on steadily increasing as the companies grow. I hope, of course, that the shareholders will support us in this scheme. I shall feel very gratified if they do, and I can only say that we, the Directors, will do all we possibly can to keep up the state of efficiency which the Company has been brought to. If any gentleman has any questions to ask before I put the motion for the adoption of the report and accounts and the payment of the dividend, I shall be happy to answer them.

Mr. PERRIN said he saw that the United Company was to be absorbed by the National Company, and he asked whether the absorption by the latter company of the Consolidated Company's customers would lessen the sale of their telephones, and whether the Company supplied the National Company?

The CHAIRMAN: Does any other gentleman desire to ask any question? The agreement which we have with the United Company will be simply handed on to the National Company. We already supply the National Company. We supply the whole of the companies in England, and therefore it will not make the slightest difference to us. In fact, to tell you the truth, I think we shall probably benefit by it. I see that there is a great possibility of this amalgamation extending the business very largely, and that means more instruments to manufacture. I have now to propose—

"*That the statement of accounts and balance-sheet and the report of the Directors as now submitted to the meeting be received and adopted, and that a final dividend of 7 per cent. for the half-year, making, with the interim dividend previously paid, 6 per cent. for the year ended March 31, 1889, be paid.*"

Sir A. ARMSTRONG, K.C.B., seconded the motion, which was carried unanimously.

The CHAIRMAN next proposed the re-election of the retiring directors, Mr. J. H. Buckingham and Mr. Richard Van Zeller, who, he assured the shareholders, were excellent servants of the Company and valuable members of the Board.

Sir A. ARMSTRONG, in seconding the motion, endorsed the remarks of the Chairman.

The resolution was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. H. GRÆWING, Mr. J. G. Griffiths was re-elected an auditor to the Company, the Chairman stating that he was very much satisfied with the way in which Mr. Griffiths kept the accountant up to his work.

Mr. RAINES afterwards moved, and Mr. GARDINER seconded, the re-election of Mr. A. E. Green, the other auditor, and the motion was also adopted.

The SECRETARY then read the notice convening the extraordinary meeting, the advertisement stating that the following resolutions would be submitted:—

"*That the capital be increased to* £307,545 *by the creation of* 75,000 *new shares of* £1 *each.*

"*That the new shares be called Preference Shares, and that the holders thereof be entitled to a preferential dividend at the rate of* £6 *per cent. per annum, payable out of the profits of each year, without any right in case of deficiency to resort to the profits of subsequent years.*

"*That the holders of the said Preference Shares shall be entitled on any distribution of the assets of the Company to be repaid in the first place the amount paid up on the Preference Shares held by them respectively, before any payment out of such assets to the other members of the Company.*"

The CHAIRMAN: I do not think, after the explanation that I gave, it will be necessary for me to go over the ground again, and therefore if it is your pleasure I will simply put this resolution to you as a whole. We

Digitized by Google

might take them separately, but I think it would be quicker to take them as a whole. He accordingly proposed the resolutions as one.

Sir A. ARMSTRONG seconded the motion.

Major-General WESTROPP said that it was now proposed to increase the capital of the Company, whereas two or three years ago the capital was reduced by a return of 1s. a share to the shareholders, and some time before that the capital was reduced from 20s. a share to 15s. a share, the shareholders being mulcted of the 5s. If they were now to increase the capital of the Company he would like to know why they had received that shilling back. Would it not have been more useful to have kept it for the purpose for which money was now required.

Mr. LEATHERBARROW asked whether the Directors were satisfied with the securities they would receive from the subsidiary companies for the proposed advance to them of the £15,000.

The CHAIRMAN: Has any other shareholder any question to ask? Receiving no response, he continued: The first question was as to a quotation on the Stock Exchange. Until we have absolutely issued 50,000 shares no quotation could be granted on the Stock Exchange. I now come to the question about the return to the shareholders of 1s. a share. Of course, if we had kept that shilling we should have had money to advance to our subsidiary companies, but I confess I cannot see that it makes very much difference. It occurs to me that having given you back that shilling we have paid the shareholders a great deal more dividend on the 14s. remaining. As to the 5s. that was deducted, that was a different matter altogether. That event occurred before this Board came into office, and that was money that was lost by our predecessors. In the one case the shares were reduced by 5s. because that money was lost, and in the other case we returned them 1s. a share. It appears to me that there is a great deal of difference in the two proceedings. If the old Board had returned you 5s. instead of losing you 5s. that would have been doing what we have done. The other question asked was whether the Board are satisfied that we are going to get securities from the sub-companies which will be dividend-paying securities. Of course we are, or we should not propose what we are going to do. It is true that we hold a large portion of the debentures of these companies, but they have Preference shares and Ordinary shares which will pay dividends, and that will pay us a return on the money we propose to advance.

Major-General WESTROPP thought that before the capital of the Company was further increased the Directors should try and return what the former Board had taken away, and so make the shares their original value.

The CHAIRMAN: I do not think that that is possible or practicable. We have no capital to return. If you would like to have no dividends and receive the money back in that way you could get it; but I see no other way.

Mr. A. H. PINTO stated that as the Directors proposed to issue Preference Shares the Ordinary Shares would be affected; and he therefore asked if the holders of the Ordinary shares would be afforded the opportunity of exchanging them for Preference shares.

The CHAIRMAN: We have very carefully considered this. It has not been done hastily, but we could not, of course, do what this gentleman suggests. There would be no object in it. In my mind, this proposal of ours is going to increase the value of the Ordinary shares—that is my object—and not to depreciate them. He then put the motion, which was carried unanimously, and he subsequently announced that the dividend warrants would be posted on or before Tuesday.

Mr. BUCK proposed a vote of thanks to the Chairman, observing that the shareholders ought to congratulate themselves on having such a gentleman to preside over the interests of the company. He (the speaker) was an original shareholder, and he felt very much gratified at finding that the present Board were discharging their duties so satisfactorily to everyone.

Mr. HEYER seconded the motion, which was carried unanimously.

The CHAIRMAN: Gentlemen, I am very much obliged to you. As long as I possibly can you may be quite sure that I will watch over your interests and do the best that any man can do for you. I cannot say more than that.

The meeting then separated.

Hastings Electric Light Company.

The annual meeting of this Company was held on the 22nd inst. at the Works, Hastings, Mr. H. M. Baker, J.P., presiding.

In presenting their statement of accounts for the year ended March 31, the directors stated that in accordance with the views expressed in their report for 1888 as to laying new mains and procuring additional plant, they had purchased and fixed a new steel boiler on the premises at a cost of £749. 13s. 9d., and new mains had been laid, in order to extend the supply, at a cost of £284. The demand for incandescent lighting increases, the Company now supplying 984 lights, as against 864 per last report. The Directors, however, feel that an enormous increase could be made at once if sufficient capital was available for laying down new mains, and they are not without hope that arrangements may be made by which public and private lighting by electricity may be vastly extended. The revenue accounts showed a profit of £432. 2s. 10d.; from this must be charged the interest paid to bankers, £204. 0s. 6d., and interest on debenture bonds, £50, thus leaving a net profit for the year of £178. 2s. 4d., which, added to £108. 19s. 4d. brought forward from the last account, makes the sum of £287. 1s. 8d. available for dividend, out of which the Directors proposed to pay 5 per cent. free of income tax, which will amount to £205. 10s., and to carry forward the balance to the next account.

The CHAIRMAN, before moving the adoption of the report, read a letter from Mr. R. Hammond, expressing gratification at the report and regret that he could not attend the meeting. He urged the Directors to make application to Parliament this year for a Provisional Order, the first step being to go to the Corporation. Proceeding, the Chairman remarked that the Directors had that day completed seven years' service without fee or reward, and their services had been of no light character, but at times exceedingly onerous and difficult. They had had struggles such as few companies had had to contend with, but they were perfectly satisfied with the state of the electric light in the town, their primary object having been to promote the public interest. Two years ago they proposed to raise £5,000, but the response was simply *nil*. By personal application to several of their friends £1,000 was then subscribed in debentures, and with that they were just able to lay down additional plant and keep their heads above water. They could now double the amount of business if they had sufficient capital to develop it. He called attention to Mr. Hammond's letter because the Directors had decided to make application for the Provisional Order. Allusion was made in the report to the fact that arrangements might be made by which public and private electric lighting might be vastly extended. He did not think it would be advisable in public meeting to state what arrangements they contemplated, but they thought seven years was a long enough period to have devoted their energies to the Company. Therefore something would have to be done, and that soon. Owing also to the lack of interest taken in most public matters in Hastings the capital of the Company from the first was very meagrely subscribed, and Messrs. Beeching, the bankers, assisted them in developing the Company by a mortgage which they now wished to have paid off, and that was another reason why some arrangement must soon be made. Referring to the approaching advance of electric light in London and in Folkestone, he said that whatever might take place with reference to the Hastings Company they might claim that up to the present time there was no town in England where the electric light had been better supplied and with greater success, except from the shareholders' point of view, than had been the case at Hastings. The balance-sheet showed an expenditure of some £14,777. Whether that money has been well spent or whether

they had got full value he was not going to say; but against it there was capital subscribed, £6,855; debenture, £1,000; and mortgage, £4,000; making together, £11,855, which left a balance of £2,922. Therefore, as a going concern, they had not got a very bad article to dispose of if they wanted to sell it. In all probability before another annual meeting came round the shareholders would be called together for some special purpose with reference to what he had already reverted to. In conclusion, the Chairman mentioned that the dividend would be paid as soon as possible.

Mr. REEVES seconded, and the report and balance-sheet were adopted.

Mr. J. WOODHAMS, in eulogistic terms, moved the reappointment of the Chairman and Councillor Roddis as Directors.

Mr. F. A. LANGHAM, in seconding, agreed with the Chairman that something must be done to start the Company with renewed life or wind it up, or at all events the present Directors should be relieved from the duties of office. He hoped that Hastings having been one of the pioneers in electric lighting would not drop it for others to take up. He was sure the townspeople would not like to see it dropped.

The CHAIRMAN, in replying, referred in high terms to the services of the Secretary and Mr. Mercer, the manager, and to the magnificent lighting of the Health Exhibition and its grounds by the Company.

United Telephone Company (Limited).

Report of the Directors for the year ending 30th April, 1889, to be presented to the shareholders at the ninth annual ordinary general meeting of the Company, to be held at the Cannon-street Hotel, London, E.C., on Tuesday, the 4th June next, at half-past two o'clock:—

Capital Expenditure.—A reference to the capital account will show that up to the 30th April, 1889, the sum of £299,211. 8s. 9d. has been expended upon the works in connection with the Metropolitan District and Instruments on Royalty in the Metropolitan District and Subsidiary Companies, being £35,334. 17s. 11d. more than the outlay shewn in the last balance sheet.

Revenue.—The revenue accounts, exclusive of Metropolitan District Royalties, show that the receipts of the Company from all sources properly attributable to the year have been £152,804. 10s. 9d., as against £143,134. 18s. 5d. in the preceding year, or an increase of £9,669. 12s. 4d.; and the expenditure has been £58,540. 12s. 2d., as against £73,519. 8s. 8d., or a decrease of £14,978. 16s. 6d.

Working Expenses.—Metropolitan District.—The working expenses for the year have been £36,895. 9s. 5d., as against £35,724. 12s. for the preceding year, or an increase of £1,170. 17s. 5d.

Dividend.—The balance of net revenue account is £87,642. 0s. 5d., of which amount the sum of £25,000 has been absorbed by the payment of an interim dividend at the rate of 10 per cent. per annum for the first half-year ending 31st October, 1888, and the Directors recommend a further dividend of 12s. 6d. per fully paid £5 share for the second half-year ending 30th April, 1889, amounting to £62,500, making a total dividend of 17½ per cent. for the year, leaving a balance of £142. 0s. 5d., which has been carried to the reserve account.

Reserve Account.—The reserve account has been increased during the year by the sum of £9,680. 3s. 3d.

The Compagnie Continentale Edison.

In the report recently issued by the Directors of this Company it is stated that the past year was signalised by an incontestable progress in the electrical industry generally. The Paris Municipal Council had authorised the lighting of the capital by electricity. This decision gave a special importance to the Company's undertaking, and last year they acquired the electric station of the Cité Bergère, and obtained from the municipality the concession for a part of the canalisation of the City of Paris, which has for its base the line of the Grand Boulevards, from the Faubourg St. Denis to the Grand Hôtel. The works were begun, and the central station of the Cité Bergère will furnish the electric current for the lighting, under the contract secured by the Company for a portion of the Boulevards. This station, which formerly supplied 1,000 lamps, now supplied about 4,000. They had finished the station in the Cour d'Honneur of the Palais Royal, which enabled them to connect the working of the Comédie Française and the Palais Royal Théâtre to the lighting of the various shops and galleries. This station began work at the commencement of the year. These two stations have necessitated the employment of a large capital, which during the last financial period has been unproductive. This accounted for the small dividend which was proposed, but there was reason to regard the future of the company with confidence. The lighting which they had undertaken had given the best results. They had obtained a grand medal of honour at the Barcelona Exhibition. Electric lighting and the transport of power will extend greatly in France, thanks to the Exhibition. They had ceded their patents for the manufacture of lamps to the Compagnie Générale de Lampes Incandescent. That company gave them in the first half-year of its existence 6 per cent. per annum, at the same time putting by a large reserve. Taken altogether, the working for the year 1888 shows a profit of 262,066 francs, which they propose to divide as follows:—5 per cent. to the reserve, making 13,103 francs; 4 per cent. interest on the shares, *pro rata temporis*, or at the rate of 20 francs for the 7,000 old shares, making 140,000 francs; and at the rate of 12 francs 91 centimes for the 7,000 new shares, making 90,416 francs. These sums together make a total of 243,519 francs, and leave a balance of 18,546 francs to be placed to the profit and loss account for 1889. Again, after a distribution of 42,000 francs, at the rate of 3 francs per share, on the 14,000 founders' shares of the company, there remained a balance of 8,545 francs, which it was also proposed to distribute.

NEW COMPANIES REGISTERED.

HALIFAX AND BERMUDAS CABLE COMPANY.—The Capital and Counties Bank has been authorised to receive subscriptions for £120,000 Four and a-Half per Cent. Debentures of this company at the issue price of £102 for each £100 bond. According to the prospectus the proceeds of the loan are to be devoted chiefly towards the construction and laying of a telegraphic cable between Halifax, Nova Scotia, and the Bahamas. The sum of £15,000 is to be deposited with the Government as security for the due performance of the contract. The Government has agreed to pay the company an annual subsidy of £8,100 for twenty years, and this sum will be devoted to the service of the debenture debt. The subject is further dealt with in our Leading Article.

THE PORTSMOUTH AND SOUTH HANTS ELECTRICITY SUPPLY COMPANY.—On the 23rd inst. a company was registered under the name of the Portsmouth and South Hants Electricity Supply Company (Limited), with the nominal capital of £50,000, for the purpose of supplying Portsmouth and the vicinity with the electric light.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 24, 1889, amounted to £5,313.

HAMBURG-HELIGOLAND CABLE.—Since the 1st April this cable has become the property of the German Government, and the old company is now in liquidation.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY.—The numbers are announced of 72 bonds, amounting to £7,200, of this company's Six per Cent. Mortgage Debentures, to be paid off at par at the offices of the company, 106, Cannon-street, E.C., on and after June 29 next.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 24, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,813.

BUSINESS NOTICES.—Messrs. W. H. Willcox and Co., of 36, Southwark-street, London, S.E., announce that they have taken over the premises, business, goodwill, and stock of Messrs. W. Goodwin and Co., leather machine band and hose pipe manufacturers, &c., and are now giving special attention to this department.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

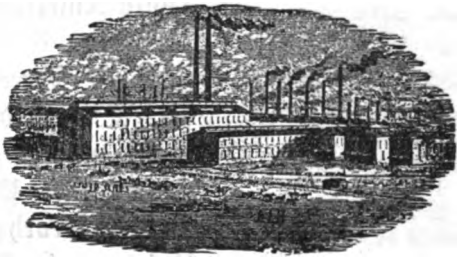
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 577.—Vol. XXIII. FRIDAY, JUNE 7, 1889. Price Fourpence.

NOTES.

The Board of Trade has refused the application made by the Brighton and Hove Electric Lighting Company for a Provisional Order for that district. It will be remembered that an Inquiry was held in Brighton on April 11th (see *The Electrician*, April 19th), when it appeared that the application was strenuously opposed both by the Brighton Corporation and the Hove Commissioners. The application for a Provisional Order made by the Corporation of Swansea has been granted.

We are happy to find that the London County Council has raised no objection to any portion of Major Marindin's proposals. The Council is, however, of opinion that "as the representative governing body of the whole of London it should be appointed the controlling authority." From the text of their letter (which will be found in another column) it is plain that the Council has no very clear idea as to the existing division of responsibility betwixt the local authorities and the Board of Trade, but if its ambition will be satisfied by a transfer of the functions at present exercised by the local authorities we see no reason to object. The Supply Companies in the Metropolitan district would be better off in having to deal with a single authority in place of the existing twenty-nine. On the other hand, it would certainly be wiser to allow the question to rest for a year or two whilst the Council is getting fairly into harness. As to transferring to such a body any portion of the specific duties of the Board of Trade, we think that nothing could be more objectionable;—happily this is not a question of practical politics. The Council proceeds in a light-hearted sort of way to talk of the probability of its undertaking the wholesale construction of subways into which all wires should be "compelled" to go. From the point of view of the electrical interests nothing could please us better. By all means construct adequate subways throughout the town; we can promise that there will be no difficulty in getting the companies to use them. But what will the ratepayers have to say? Has the Council formed any idea of the probable cost?

At the meeting of the Committee of the Electrical Trades Section of the London Chamber of Commerce, held on Monday afternoon, it was decided to hold an Extraordinary General Meeting of the Section on the 24th inst., when a report will be presented. It is also proposed to follow the precedent of the Council of the Chamber of Commerce by inviting the members to attend all the meetings of the General Committee, any member being entitled to speak upon any subject on previously giving notice of his intention to the Chairman. Arrangements will probably be made to publish the agenda in the technical journals the week previous. A copy of the proposed Regulations relating to Overhead Wires was received from the Board of Trade, and referred to the Committee already sitting. It was decided to ascertain whether, as a step towards uniformity of gauge, the trade in general is disposed to adopt the "British Association" Screw Threads. The project for establishing a Standardising Laboratory has advanced a further stage, and a meeting of the joint Committee (of the Section and the Institute) was held on Wednesday last, when a detailed scheme which had been drawn up by a sub-committee was provisionally adopted.

Major Flood Page has addressed a letter to the daily papers on the subject of Major Marindin's report, with which the majority of our readers can scarcely fail to find themselves in agreement. The writer bears testimony to the general fairness and independence of judgment which characterises the report, but his chief object is to draw attention to the importance of the step about to be taken by the Board of Trade in the issue of a Model Provisional Order. This, indeed, in our own view, is a task requiring a degree of knowledge, skill, and judgment fully as great as that demanded for the work hitherto accomplished, whilst it has a far wider import for the industry at large. And although we have reason to place confidence in the wisdom of the Board of Trade and its advisers, yet we would emphatically endorse the view of Major Flood Page when he says: "Whatever care may be bestowed on the drafting of the Model Provisional Order, provision should be made for its easy and inexpensive amendment as the necessity for change becomes manifest." The writer goes on to express the belief—about which there can scarcely be two opinions—that "no body of men are yet sufficiently acquainted with the development that electric lighting will take to draft an unalterable Model Order." In concluding his letter the Major instances the fact that already since the issue of the report the question of alternating motors has undergone fresh development at the hands of Mr. Mordey, and probably also by Ganz, of Buda-Pesth.

With regard to the issue of a Model Order, it appears to us that the chief difficulty will be to find any stereotyped formulæ whatever to cover all the multitudinous possibilities incidental

Digitized by Google

to variations of Time and Space, to say nothing of System. It would at least seem necessary to provide alternative readings for many of the clauses.

THE issue this week of the prospectus of the Electric Construction Corporation (Limited) may probably be taken to mark the advent of a new era in the history of electrical engineering in this country. We saw last year that the City would find money for well-considered and properly backed-up schemes for Electricity Supply Companies, but in the successful floating of an undertaking for the manufacture of electrical apparatus and the erection of electrical plant a very distinct step in advance has been made. The Company in question has been formed for the amalgamation and purchase of the follow-lowing undertakings:—Elwell-Parker (Limited), of Wolverhampton; the Electrical Power Storage Company (Limited), the Railway Electrical Contractors (Limited), the Julien Patents for the United Kingdom for Electric Traction, and the Sprague Patents for the United Kingdom. The two first-named are perfectly well known throughout the entire electrical world as amongst the earliest formed and most extensive concerns in this country. The Railway Electrical Contractors (Limited) is a smaller affair, but one whose future was in any case well assured. Our readers are aware of the successful work carried on for many years on the Brighton line, and of the recent partial introduction of the system on the Midland Railway. With the two latter Companies, both of foreign origin, we cannot profess to be so well acquainted. The combination will, no doubt, be strengthened by their accession; and as for the Sprague business it is well known as being one of the most successful electric traction undertakings in the United States. It will thus be seen that the Corporation is, or should be, well equipped for almost every kind of undertaking connected with electrical engineering, and under reasonably good management it can scarcely fail to attain a markedly successful future. Something, of course, depends upon the *personnel* of the technical staff, and we trust that a judicious selection will be made.

IT was a most unfortunate "concatenation of circumstance" which reduced the period available for the discussion of Mr. MORDEY'S Paper to a single hour. Had the Fates been reasonably propitious a Paper of such quality (and dimensions) might well have occupied the attention of the Institute for three whole evenings at the least. However, it is useless to indulge in vain regrets, and we have at any rate the gratification of recognising that such discussion as the Paper did receive was quite of the highest order almost throughout. Prof. FORBES, on behalf of Dr. HOPKINSON, did well to call renewed attention to his (Dr. HOPKINSON'S) Paper of 1884 (see *The Electrician*, Nov. 15, 1884), in which the theory of alternators received well-nigh complete development. Dr. HOPKINSON'S equations show that the most favourable condition for parallel working is attained when the period is equal to 2π times the time-constant of the circuit, so that it is not necessary to aim at the reduction of the self-induction without limit. We need hardly emphasise the value of the knowledge of this relation, but it seems almost a pity that Dr. HOPKINSON allowed the profession to remain so long oblivious to the discovery which he had placed on record.

MR. KAPP seeks to reconcile the theory with which his name and that of Prof. FORBES is identified with the experiments of Mr. MORDEY by assuming that when the coils of the armature are directly opposite the pole face "its self-induction is nearly as great as if the iron passed right through," and that in this position the self-induction is "far greater" than it is when the coils are in the intermediate position. This conclusion is not borne out by the secohmmeter measurements made by Prof. AYRTON'S students, in which the difference was shown to be little more than 5 per cent., and the variation is actually in the opposite direction. We do not, however, feel sure that this discrepancy is in itself sufficient to entirely vitiate Mr. KAPP'S argument, which, though it undoubtedly requires modification, seems to us to have some solid foundation. The reaction is evidently extremely complex, and probably a mathematical investigation would show that certain factors assume greater relative importance than at first sight appears. It is a pity that we have no measurement of the self-induction of the armature itself when clear of the field magnets. It will be remembered that in one of the experiments a machine, excited to 2,000 volts, was made to drive as a motor a similar machine excited to only 1,000 volts, and that each voltmeter then read 1,500. Mr. KAPP seeks to explain this by the demagnetising action of the armature upon the field of the generator and the reverse effect upon the field of the motor. It seems difficult to believe that this is the true explanation—if it were, the self-induction of the armatures would necessarily be enormous, and we should expect to find an altogether disproportionate waste of energy in the heating of the unlaminated pole pieces. Besides, as Prof. S. P. THOMPSON pointed out, 1-200th of a second is not long enough for such a reaction to take place. It seems, moreover, unnecessary and erroneous to assume that the back E.M.F., *due to the field of the motor*, is itself raised from 1,000 to 1,500 volts. Under the conditions of the experiment the two voltmeters were virtually coupled terminal to terminal, and must necessarily give the same indication. The whole question will doubtless before long receive further elucidation.

OUR New York correspondent sends us this week a detailed account of what cannot fail to be considered one of the most extraordinary achievements of mechanical and electrical engineering on record. His letter contains also a description of the Thomson-Houston Electric Railway at Topeka—the largest undertaking of the kind yet in existence.

Sebastopol.—The municipality of Sebastopol have decided to light the town by electricity, and tenders will shortly be asked for.

Swansea.—Consent has been obtained from the Board of Trade to the application of the Corporation for power to light the borough by electricity.

Royal Society.—The following Paper was down for reading yesterday afternoon at the Royal Society: "Electro-Chemical Effects on Magnetising Iron," by T. Andrews, F.R.S

Digitized by Google

The Lighting of Dublin.—Hastings was last week visited by a deputation from Dublin, who went there for the purpose of making inquiries concerning the question of electric lighting.

Honours.—*Indian Engineering* says that Mr. Barker, who had charge of the telegraphs in the Black Mountain Expedition, has been awarded the Companionship of the Indian Empire.

The Electric Light in Yucatan.—Mexican advices state that the city of Merida, the capital of Yucatan, was on April 3 lighted by electricity. The plant was erected by American electricians.

Paris.—The first of a set of three cars driven by electricity has been running for the last few days on the Madeleine-Porte-de-Courcelles Tramway. The car is of a heavy description, and carries 49 passengers.

Llandudno.—The Pavilion and Pier Company at Llandudno are laying down an engine and apparatus for lighting up the pavilion and pier, and the George Hotel is already fitted throughout with the electric light.

Sheffield.—The *Sheffield Daily Independent* notes that 55,538 messages were sent through the office of the Sheffield Telephone Exchange and Electric Light Company during the week ending May 24th, as against 23,904 messages in the corresponding week of last year.

Smart Work.—We learn that the result of the Derby, which reached the Direct United States Cable Company's Throgmorton-street office at 3h. 8min. 30sec. p.m. from Epsom, was transmitted to New York and delivered to the addressee at 3h. 8min. 32sec. p.m (Greenwich time). This beats all record.

Institute of Electrical Engineers.—On Friday evening last, by kind permission of Mr. Spagnoletti, the students visited the electric light station of the Great Western Railway at Paddington. They were conducted round the station by Mr. Walton, who explained the whole of the working to them, the visit being both pleasant and profitable.

Telegraphic Communication with South Africa. — The Eastern Telegraph Company announces the opening for traffic of the Eastern and South African Company's new West Coast cable to Cape Town. This will afford an alternative means of telegraphic communication with South Africa. Telegrams can be sent by either the East or West Coast cable routes at the same tariff.

The late M. Gaston Planté.—M. Gaston Planté has bequeathed to the Academy of Sciences a sum that will admit of the award of a prize of 3,000fr. every second year to some Frenchman who has distinguished himself by a study of the science of electricity. In addition, M. Planté has left his house and large gardens at Bellevue, near Paris, as a place of retreat for poor scientists.

Personal.—Mr. J. Carruthers Allan, lately representing the African Direct Telegraph Company at Lagos (West Africa), and also holding the post of His Danish Majesty's Consul at that port, had the honour of being presented at Court and of an audience with H.R.H. the Crown Prince of Denmark during a recent visit to Copenhagen. Mr. Allan is now proceeding to take temporary charge of the above company's station at Bonny.

Institution of Civil Engineers.—The Council has awarded the following premiums in respect of the original communications on electrical subjects submitted during the session 1888-89 :—A Telford medal and a Telford premium to Gisbert Kapp, Assoc.M.Inst.C.E., for his Paper on "Alternate-Current Machinery." A Miller prize to Samuel Joyce, jun., Stud.Inst.C.E., for his Paper on "Electrical Measuring Instruments: their Properties and Calibration."

Florence.—A Belgian company, the Société Anonyme Belge pour l'Éclairage et Transmissions Électriques à Longue Distance, has obtained a 40-year electric lighting concession for the towns of Florence and Pistoria. The system employed will be that of M. Léon Gérard, who uses accumulator sub-stations. The company has already applications for over 6,000 lamps for a minimum period of three years. M. Gérard's method has been for some time in successful operation in Brussels, at the Théâtre de la Monnaie.

The Telephone in Java.—In Java, under the rule of the Dutch Government, great progress is being made as regards the use of the telephone. During the past year five concessions were granted for erecting telephonic lines at various places throughout the island. In the interior of the island seventeen places where the telegraph does not exist have been connected by the Government to the nearest telegraph stations by telephone. In Batavia, Samarang and Sourabaya the telephone has met with great success, and is highly appreciated.

Telephone Patents in France.—In 1882 the Société Générale des Téléphones seized a number of telephone instruments in Paris and the provinces, which they held to be infringements of the patent rights held by the Société. The confiscation of these telephones was demanded, together with damages, and the insertion by the defendants of the judgment in twenty French and foreign papers. "We learn, however," says, *Industria*, "that M. le Procureur de la République has finally refused the demands of the Société Générale des Téléphones."

Holborn Board of Works.—At the meeting of this Board on Monday last a letter was received from the Board of Trade stating that electric lighting companies would be compelled to lay mains in the list of scheduled streets within a specified time. In the determination of this list the Board would be largely influenced by the views of the local authorities, therefore they would be glad to receive from them at the earliest possible period a list of the streets in their district which in their opinion should be so scheduled. The communication was referred to the Works Committee.

Montevideo.—In 1887 the Montevideo Electric Lighting Company obtained a concession for the public lighting by electricity on condition that it carried out the street lighting within eleven months. Although the period has been twice extended—first for nine months and then for five and a-half months—nothing has up to the present been done. The gas company has now entered a formal protest against this concession and the extensions of time as a violation of their contract with the authorities, which gives them the preference on equal terms over any other company offering to undertake the public lighting.

Haarlem.—The Haarlem Scientific Society asks for Papers on the two following electrical subjects, the competition to remain open until January 1, 1890 :—1. An experimental or theoretical investigation extending our knowledge of inductive and electro-dynamic phenomena. 2. An experimental or theoretical determination for one or several substances of the influence exercised upon specific inductive capacity by compression in the direction of or perpendicular to the E.M.F. These Papers may be written in English, French, German, Italian, Dutch, or Latin, and must be sent, accompanied by a sealed envelope containing the name of the writer, to the Secretary of the Society, Prof. J. Bosscha.

Copper.—The new copper combination, as to which so many conflicting reports have been current, says the *Financial News*, is, it seems, going to pull through after all. Yesterday the last of the American companies which had been standing out came to terms, namely, the Yamarack. The English companies have only been waiting for the Americans, and a similar agreement among them is practically assured. The effect of this arrangement will be to relieve the copper market for a considerable period from any risk of having the defunct Syndicate's stock thrown on to it. Manufacturers, being freed from that danger, will now buy more freely, and a gradual advance in price to about £45 per ton is aimed at.

Theatre Lighting.—At Magdeburg the town theatre has replaced gas by the electric light. According to the *Gas World* the average quantity of gas previously consumed was 2,224,971 cubic feet in the season. The engines put in were two Otto (Deutz) 40-horse, one five-horse Otto, and a two-horse gas motor; and three continuous-current dynamos, Edison pattern, 240, 240 and 30 amperes, all at 105 volts tension. The lamps are glow-lamps, 75 of ten, 433 of sixteen, 356 of twenty-five, and 160 of thirty-two candle power. The orchestra is lit up by gas; the passages have electric light, gas and oil lamps. During last season there were used 1,805,546 cubic feet of gas. Heating and lighting the machine-room took 77,556 cubic feet.

Digitized by Google

Cooling the machines took 212,007 cubic feet of water. The number of evenings during the season was 182, and during the season there was no hitch in the electric lighting.

The "Lancaster" Catalogue.—The 1889 edition of this well-known catalogue, issued by Messrs. Lancaster and Tonge, of Manchester, contains several important additions to that of last year. Amongst the new items we notice the "Lancaster" self-adjusting bearing, which is arranged so as to swivel in either a horizontal or vertical direction, a great advantage in the case of a crooked coupling or an untrue shaft. A magnetic indicator and high and low water alarm, devised by MM. Lethullier and Pirrel, is also described and illustrated. Besides showing the height of the water in the boiler this apparatus actuates two whistles giving different sounds whenever the water is either too high or too low. These are some of the many additions to this useful catalogue. The general appearance of this publication would, we venture to think, be considerably improved by a somewhat less liberal underlining of the testimonial pages.

Annual Conference of the Postal Telegraph Clerks' Association.—The annual conference of the Postal Telegraph Clerks' Association of the United Kingdom was held at Bristol on Saturday last, under the presidency of Mr. E. C. Taylor. The most important matter discussed was the motion of a Bristol delegate respecting payment for Sunday labour, the department at present maintaining that payment is made for two hours each Sunday, and requiring the clerks to work a full day once a month. This, it was pointed out, had always been a sore point with the clerks. Although Sir John Puleston had rendered good service to their cause, yet at a critical moment he failed to move the resolution which was expected from him in the House of Commons. Mr. Bradlaugh, however, had come to the rescue, and had a motion on the books of the House to the effect that all labour performed on Sundays should be paid for as extra duty. He was now awaiting his fortune in the ballot to bring it forward. A resolution was carried directing inquiries to be made into the pension question.

Wolverhampton.—The *Birmingham Gazette* says:—"We some time ago drew attention to the intended removal of the electrical engineering works of Messrs. Elwell-Parker (Limited), Commercial-road, Wolverhampton, to new and commodious premises about to be erected on a plot of land situated between the Stafford-road and the London and North-Western Railway at Bushbury. Owing to the extensive character of the new structure additional land was found to be necessary and 11¼ acres more ground have been purchased, and the total area of the land of the company now will be 24¼ acres. In addition to carrying on the manufacture of electrical apparatus, for which Messrs. Elwell-Parker are well known, it is intended to branch out into the making of chemical products by electro-chemistry, for which the company hold a number of patents. Amongst other matters it is proposed to turn galvanizers' waste acid or "pickle" into a merchantable commodity, a process having been discovered by the chemist to the firm which it is believed will prove eminently successful."

The Electroplating of Glass and Porcelain.—According to the *Moniteur de la Céramique et de la Verrerie*, a method of electroplating glass and porcelain has been devised by M. Hansen. The chief difficulty hitherto experienced has been to obtain a conducting surface which would not prevent the proper adherence of the metallic coating. M. Hansen uses chloride of gold or of platinum dissolved in sulphuric ether, to which sulphur dissolved in some heavy oil is added. This compound, after having been slightly heated, possesses sufficient consistency to allow of a film being laid on the glass with a brush. The object treated in this way is then moderately heated in a muffle until the sulphur and chlorine are completely volatilised, the gold or platinum adhering firmly to the surface. The best copper bath is two parts of sulphate of copper to three of distilled water. In silver plating, 17 parts of nitrate of silver and 13 parts of cyanide of potassium dissolved in 300 parts of water are used. For gold plating, seven parts of gold are used, which are preferably dissolved in aqua regia, and precipitated by means of ammonia. This precipitate, while still wet, is then placed in a warm solution consisting of 9 parts of cyanide of potassium and 90 parts of water.

Improvements in the Wimshurst Machine.—With a view of adapting it to medical purposes, M. Oudin has introduced several modifications in the Wimshurst machine. The two large glass plates are replaced by ebonite discs 50 centimetres in diameter. These discs are provided with wooden projections covered with tinfoil, so that the brushes do not touch the plates themselves. Brushes, combs and plates are mounted so that they can be easily altered as required. It is possible, for instance, to do away with two plates and transform the whole arrangement into an ordinary two-plate machine. The condenser employed by M. Oudin is of a somewhat peculiar character. It consists of glass plates 24 by 18 centimetres, on to one side of which is fastened a narrow strip of varnished tin 3 centimetres broad; these strips start from the smaller sides of the plates, and are about 17 centimetres long. The plates are arranged one on the top of the other to any required number, the ends from which the metal strips start being laid alternately left and right, and the strips themselves being connected to two metal pillars in connection with the machine. The combs employed by M. Oudin have toothed edges in lieu of the usual long projecting points.

Resistance Coils for Use with Alternate Currents.—In a Paper read before the Société Française de Physique M. Chaperon recently described a method of winding resistance coils so as to enable the Wheatstone Bridge to be employed in alternate-current work. With a telephone instead of a galvanometer, a balance, when the present form of coil is used with alternating currents, is denoted merely by a minimum of sound, not by complete silence, so that any approach to accuracy is impossible. M. Chaperon, in common with Kohlrausch, Cornu, and others, was inclined to attribute these disturbances to electrostatic rather than to inductive effects. He therefore first of all experimented with two coils identical in every respect except that one was wound as a solenoid and the other like the coil of a resistance box. Much better results were obtained with the former than with the latter, although, of course, the self-induction was much greater in the first case. M. Chaperon, therefore, while taking care to have inverse currents in the adjacent portions of his coils, endeavours to diminish electrostatic effects by arranging matters so that the difference of potential between these adjacent portions shall be a minimum. This is effected by winding the coil in several sections and taking the greatest care to keep the thickness of the insulation rigorously equal in every part. M. Cornu, who assisted M. Chaperon in these investigations, says the new form of coil gives excellent results.

The Argentine Telegraphs.—At the recent opening of the Congress the President gave the following information about the telegraphs of the Republic:—Our telegraphic management is steadily improving. Telegrams show an increase of 6 per cent. over the figures of 1887. In 1887 official messages amounted to 25,554, whilst in 1888 the number fell to 12,443, a decrease of 50 per cent.; this is due to the stoppage of the great abuse in the use of free messages. A reduction in tariffs is generally followed by a falling off in revenue the first few years, yet we see that, although the tariff was reduced 37 per cent., the revenue increased 62 per cent. New postal and telegraph offices have been opened to the number of 212; 5,359 kilometres of telegraph line have been erected, 5,062 kilometres have been repaired, 3,811 kilometres have been reconstructed, 3,529 kilometres of new line have been contracted for, making a total of 17,781 kilometres of telegraph lines. New lines built and repaired make up a total of 10,449 kilometres for the year's work, say, at the rate of 28 kilometres per day. When all the contracted lines are complete the Republic will have a complete telegraph system connecting all the principal points of the country. The first cable will shortly be laid between the capital and Rosario. With the view of extending the telegraphic service with Europe a contract has been signed *ad referendum* with Messrs. Bieckert and Co. to lay a cable from Buenos Ayres to Lisbon.

An Erratic Lightning Flash.—A peculiar case, illustrating the vagaries of lightning, is reported from Poundridge (Westchester County, U.S.A.). An old-fashioned square-built cottage, with a chimney in the centre of the roof, was struck during a thunderstorm, and two out of the eight people inside were

Digitized by Google

killed. The chimney was shattered to pieces, and the bricks were hurled yards away. The account then goes on to say that the flash separated into four main currents. "One of them flashed down the space left by the wrecked chimney, tore open the ceilings, and leaped to a stove-pipe leading to the stove in the room where the people were sitting. The chairs were split in two, the window panes were dashed from the sashes, and the door was splintered. A second current went along the roof to a tree on the east side of the house, stripped the bark from the tree and leaped 20 feet away to a fallen tree, knocking it into splinters. The third current made its way to another tree on the north side of the house, cleft it in twain, and following the course of its roots, tore up the earth on all sides. The last current spread out in opposite directions in the ceiling of the lower floor. The plastering was scattered in the finest powder, while the laths looked as if a coarse-toothed saw had cut an opening in them from one end of the house to the other. Every dish was broken to pieces, the outer walls were forced out, while the inner and less substantial walls were twisted out of shape and torn apart. Beams and boards were split and splintered into kindling-wood."

Lightning.—The following abstract from a report by a German lightning rod inspector will be of interest at the present time. Herr F. Niesen, whose Paper appears in the *Elektrotechnische Zeitschrift*, No. 689, says that for the last seven years he has had charge of the rods on the Berlin Inland Revenue buildings. At the beginning of that time he found them in a very unsatisfactory condition, and had many of them repaired. Since then all the conductors have in general lasted well—both copper rope and also iron rod and rope, the principal cause of injury arising from the presence of workmen on the roofs. Speaking of the value of resistance tests to discover faults, he considers them of great value, as he has several times detected by that means cases where the wire was eaten through by corrosion, and yet did not show it visibly without the very closest inspection; he has also detected sundry bad joints by the same means. The earth test he uses is simply to measure the resistance between the conductor and the nearest water-pipe; with an ordinary bridge of course polarisation is an objection, but is not sufficient to prevent the test showing whether the resistance is over or under two ohms, which is all that is required. Where there are several earth plates there should be means of disconnecting each of them from the conductor for testing, otherwise they may all be bad but one, and yet test as below two ohms. Several interesting strokes are mentioned. In one case, in Holland, a water mill was struck (no rod); the lightning, coming down the front of the house, broke through to the top of a looking-glass inside, and then out again at the bottom, only injuring the silvering at the point it entered and left, and at the line between the top and bottom half of the glass, which was made in two pieces. Another, and at the present time more interesting case, is that of a house with a rod, which was struck some years ago; the house was not damaged, *but a workman standing near the rod was stunned.*

Thunderstorms.—Thunderstorms of unusual severity continue to occur in various parts of the kingdom, though the number of fatalities is not above the average. A fatal accident is reported from Coston, Leicestershire, where three men took refuge from a storm in a hovel; the building was soon afterwards struck by lightning and one man was killed. On Wednesday last week a large stack of straw near Sutton was set on fire by a lightning flash. On Thursday afternoon a violent thunderstorm passed over Richmond (Yorkshire) and district; during the storm the lightning entered a house through an attic window and did considerable damage to the interior. A flash simultaneously struck the roof and went to earth down the chimney, displacing slates and bricks in every direction. On Sunday Lancashire and the Midlands were visited by a storm of extraordinary severity. At Liverpool two houses were unroofed by lightning, and a number of cattle were killed in the surrounding district. At Preston the savings bank was struck, and a woman was seriously injured. At Blackburn a chimney was split in two, and some cattle were killed in the fields outside the town. At Great Harwood a mill was fired. At Accrington several mills were reported to have been "stopped by lightning." Ringley church, near Bolton, was fired by lightning and the gas ignited. A flagstaff on the Southport Pier was shattered by a flash, while the clock tower at the cemetery was also struck, the bell being thrown down. The tower of Didsbury National School, Manchester, was fired by lightning and burnt out, and at Pendleton the roof of a house was struck and collapsed. In Westmoreland the storm was equally destructive. At Greenhead, Milnthorpe, the lightning entered a building containing some prize animals, and four were killed. At Montrose, Brechin, and the villages near Dundee several houses were struck, and a large number of horses and cattle were killed. At Errol two houses were set on fire and destroyed, and two persons were injured. At Reay, about eleven miles from Thurso, a woman was killed by lightning. Considerable damage to life and property is also reported from Cheshire, Flintshire, and Lanarkshire.

Method of Displaying the Lines of Electrical Induction.—In the *Scientific American* Mr. R. W. Chapman, of the University of Adelaide, South Australia, describes the following pretty and instructive experiments:—"Some very pretty experiments may be made, and the lines of electrical induction between two electrified bodies may be shown extremely well, by the use of the fine white needle-like crystals of sulphate of quinine suspended in a good insulating liquid, such as pure turpentine. To perform the experiments, take a flat glass dish and pour in turpentine to the depth of about a quarter of an inch; sprinkle this with sulphate of quinine evenly distributed till the turpentine assumes a milky appearance. If now a brass ball, connected by a chain with an electrical machine, be placed at one end of the vessel, and another connected with earth at the other end of the vessel, on working the machine the crystals of quinine will become polarised and take up their positions end on end, forming very distinct curved lines between the balls in exactly the same way as iron filings form in lines of magnetic induction when sprinkled over a magnet. The symmetrical lines of white crystals when shown up by a dark background look extremely beautiful. We have here the basis for a set of experiments which may be diversified to an almost unlimited extent by varying the number and shapes of the electrified bodies placed in the turpentine. The fact that there is no electrical force within a hollow conductor may be very prettily shown by connecting both of the balls in the above experiment with the machine and placing in between them a large metal ring connected with earth. The curved lines are then very distinctly shown running from each ball to the ring, but within the ring the turpentine remains in the uniformly cloudy state in which it was initially, the crystals showing no disposition to place themselves end on end. The difference in the appearance of the quinine particles outside and inside the ring is very striking. If now a small third ball be connected with the machine and placed in the centre of the metal ring, the appearance of the turpentine within the ring is entirely changed, and the crystals form in straight radial lines from the centre to the circumference. By multiplying the number of the electrified balls, charging some positively and others negatively, the resulting lines of induction may be made very complicated, but, provided that there is a fair space between the balls, the lines are always distinctly and clearly mapped out by the crystals. It is an easy matter to obtain some very beautiful figures by symmetrical distributions of the electrified bodies. In making the experiments it is very necessary that the turpentine should be pure and dry, as a very slight amount of impurity is sufficient to destroy its powers as an insulating medium. Benzine will answer, and it possesses the additional advantage of not dissolving any of the quinine; while turpentine dissolves it to a slight extent, but its specific gravity is so small that the crystals fall to the bottom of the vessel almost at once, and adhere to it, so that they will not easily take up the lines unless the experimenter be sufficiently quick to electrify the balls before the particles reach the bottom. On the whole, turpentine I have found to give the most satisfactory results. After the crystals have once been electrified inductively in this way they appear to take up the lines much more easily a second time. It seems as though the molecules do not recover altogether from the effects of the electric strain."

THE PARIS EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT).

May 29, 1889.

Of the exhibits which may be said to be complete that of the Société des Telephones de Zurich, in the Swiss Section, possesses several points of novelty and interest which are worthy of remark. Although by the name of the company one would imagine it to be wholly occupied with the construction of telephonic apparatus, an inspection of the exhibit proves this to be in fact a very small part of the company's sphere. Arc lamps, dynamos and electrical regulating appliances predominate, and bear the impress of considerable ingenuity. We give herewith a description of some of the apparatus exhibited by this company.

The ammeters and voltmeters are both constructed on the same design, which is fairly represented in Fig. 1. The needle (A) is of very thin, soft sheet iron, cut to the shape indicated, and pierced at intervals with holes. The free end enters more or less into the coil in action, and its movement is indicated by the pointer on the scale.

Figs. 2 to 6 illustrate parts of the automatic potential regulator. The action of this regulator is to vary the resistance in the circuit of the shunt coil of the field of a dynamo to compensate for any changes in the voltage at the machine terminals, whether caused by alterations in the load or speed. The solenoid in Fig. 2 is connected permanently to the two terminals of the machine, or the two points between which the potential is to be kept constant. The iron core of this solenoid is capable of moving freely within it, all friction against the sides being obviated by suspending the core with cords at either end. One end of the core is connected by a cord to a rocking lever, as shown, carrying at each end contacts dipping into mercury cups. Each contact is made by a platinum wire dipping into the mercury, and this wire is sealed in a small length of pointed glass tube fixed to the lever, the contact being continued by a flexible wire through the tube to the platinum, as shown. The mercury cups C C are of glass, and small iron plates dipping in the cups form the outside connection. The core is balanced and adjusted so that when the potential at the ends of the coil is normal it is not in a central position with regard to the coil, and therefore has play either way. The rocking lever is also in this case horizontal. It will be seen by the diagramatic connections in Fig. 6 that when the lever is horizontal the mercury-cup contacts shunt all current past the electro-magnets M M which actuate the regulating mechanism, but that when one contact is broken the current passes through one of the electro-magnets and attracts the central armature (Fig. 3) to that side. The mechanical arrangement for moving automatically a resistance switch backwards or forwards is effected in the following way:—The grooved pulley P (Fig. 3) is driven by a band off the dynamo or any countershafting connected to it. Fixed to and turning with the same shaft are two friction pulleys F F, while between them is the pulley A, which is only set in motion when it touches one of the running pulleys at its side, its direction of rotation depending on which pulley it touches. In Fig. 4 it will be seen that this pulley is connected to a long horizontal shaft carrying at its further end a worm; the switch carrying the toothed wheel into which this worm gears is shown removed in Fig. 5. This switch fits on over the upright spindle S (Fig. 4), and when so fixed is turned round slowly by the worm in either direction according to the direction of rotation of the shaft, and inserts or cuts out resistance accordingly. A coupling is inverted in the shaft so as to allow a small lateral play to the central pulley.

It will now be understood that the apparatus automatically adjusts the resistance either way according as to whether one electro-magnet or the other is operated. The arc lamps exhibited are designed with a worm feed motion. The shunt coil, by means of a circuit interrupter, actuates a paul and horizontal ratchet wheel, which rotates a vertical shaft. This shaft carries two worms, each acting on toothed wheels. The upper and lower carbons are each gripped between a pair of wheels, of which one is free to move and the other is actuated by the worm. The double rate of feed of the upper carbon is effected by employing a worm of double the pitch.

Six dynamos ranging from one to 40 horse-power are exhibited, and are built as indicated in Figs. 7 and 8. Simplicity of construction, external protection to the machine, as well as a good magnetic circuit, is secured by the form of field-magnets adopted. The machines are constructed to give 110 volts or 65 volts, the largest type shown developing 240 amperes at 110 volts and 750 revolutions, and weighing in all 5,900lb.

The same company also exhibit a distance water-level indicator, which depends for its action upon magneto currents. The usual float and counterpoise actuate a drum, which raises one of two levers, according to which way the drum is moving. The levers are weighted at their free ends, and when one is lifted, owing, say, to the float sinking and turning the drum one way, it is released by a detent after being lifted through a certain distance. In falling it causes the rapid rotation of the small armature of a magneto machine, and sends a current in such a direction that the indicator of the level is made to move back one degree. Similarly, the reverse action of the rising of the float causes the other lever to be lifted and let fall again, so that an opposite current is sent through the indicator, moving it forward one degree. Two of the smaller dynamos are coupled together to be run one as a motor and to drive the other as a dynamo for lighting the stand, but current is not yet supplied to it.

Electrical transmission of power will be well demonstrated. The Oerlikon Works, who have a fine exhibit, and are lighting by their system of arc lamps a portion of the Machinery Hall, have a transmission plant, in which the motor in another Section will develop 250 horse-power, and be used for driving a length of main shafting. The generator is a 300 horse-power four-pole dynamo, run by a compound condensing engine. These works will also run an exhibit of machine tools by electric motors from a 20 horse-power direct coupled engine and dynamo. A 60 horse-power combined engine and dynamo will run the lighting in the hall and supply current for motors. The switchboard will attract a great deal of attention. An automatic switch prevents injury to the machines on the transmission of power circuit by short-circuiting the field of the generator on any great excess of current occurring.

The Thomson-Houston International Electric Company are running an 80 horse-power dynamo generator at 500 volts potential, by which a 45 horse-power motor will be run in the American Section of the Agricultural Annexe to supply light and power. This company will also light the American Section, and will run a 35 arc lamp machine, a 500-light machine on the alternating-transformer system, and one of 300 lights on the alternating compensating system.

Further great interest will centre round the two systems of electric 10-ton cranes, now working, both as to their mechanical and electrical arrangements.

The first to be set to work was that under the control of Messrs. Bon and Lustreman, and is worked by a Gramme motor and dynamo, the latter being run by a Westinghouse engine in a shed some distance from the crane.

Paris, *June* 4, 1889.

The "Palais des Machines" and the so-called "Galerie de Thirty Mètres" have, since the 15th, been opened every night to the public, and the whole of the electrical illumination of the "Champ de Mars" may now be considered as complete. The same cannot be said of the lighting of the "Esplanade des Invalides," but after the trials of a few days ago it may be hoped that in the immediate future this interesting part of the Exhibition will also be able to be visited at night. The light is generally good, but it is not sufficient, and it will be necessary to increase its intensity at some points, especially in some parts of the side gardens and on the banks of the river. The Electrical Section is now very nearly finished. There are altogether over 600 exhibits, of which 480 are entered by French firms. The English electrical firms exhibiting are only 17 in number, whilst the abstention of the German electricians is complete.

The lighting of the line of the Boulevards from the Place de l'Opéra to the Place de la Concorde was commenced last Thursday; the light, furnished by 50 Thomson-Houston 2,000 candle-power arc lamps, is good, and very much appreciated by the public. They burn from half an hour after sunset up to

two in the morning. The rest of the Boulevards, from the Place de la République up to the Opéra, will have received the light by the time this letter is published, as well as the Rue St. Lazaire and the entrances to the Gare de l'Ouest. The Terminus Hôtel of this station was inaugurated a few days ago. It is entirely lighted by electricity. The motive power is furnished by two 150 horse-power (nominal) engines, but they are only provisional, and will be removed as soon as the Cie. du Secteur de la Place Clichy has its central station ready to furnish the current.

MR NIKOLA TESLA ON THE GANZ ALTERNATING-CURRENT MOTORS.

Mr. N. Tesla has addressed the following letter to the Editor of the *Electrical World* of New York :—

"SIR: About a year ago I had the pleasure of bringing before the American Institute of Electrical Engineers the results of some of my work on alternate-current motors. . . By one of the most curious coincidences, however, Prof. Ferraris not only came independently to the same theoretical results, but in a manner identical almost to the smallest detail. Far from being disappointed at being prevented from calling the discovery of the principle exclusively my own, I have been excessively pleased to see my views, which I had formed and carried out long before, confirmed by this eminent man. In his able essay Prof. Ferraris omitted to mention various other ways of accomplishing similar results, some of which have later been indicated by O. B. Shallenberger, who some time before the publication of the results obtained by Prof. Ferraris and myself had utilised the principle in the construction of his now well-known alternate-current meter, and at a still later period by Prof. Elihu Thomson and Mr. M. J. Wightman.

"Since the original publications, for obvious reasons, little has been made known in regard to the further progress of the invention ; nevertheless the work of perfecting has been carried on indefatigably with all the intelligent help and means which a corporation almost unlimited in its resources could command, and marked progress has been made in every direction. It is therefore not surprising that many, unacquainted with this fact, in expressing their views as to the results obtained have grossly erred.

"In your issue of May 4 [*Electrician*, April 19, p. 671] I find a communication from the electricians of Ganz and Co., of Budapesth, relating to certain results observed in recent experiments with a novel form of alternate-current motor. I would have nothing to say in regard to this communication unless it were to sincerely congratulate these gentlemen on any good results which they may have obtained, but for an article, seemingly inspired by them, which appeared in the London *Electrical Review* of April 26, wherein certain erroneous views are endorsed and some radically false assertions made, which, though they may be quite unintentional, are such as to create prejudice and affect material interests.

"As to the results presented, they not only do not show anything extraordinary, but are, in fact, considerably below some figures obtained with my motors a long time ago. The main stress being laid upon the proposition between the apparent and real energy supplied, or perhaps more directly upon the ratio of the energy apparently supplied to and the real energy developed by the motor, I will here submit, with your permission, to your readers the results respectively arrived at by these gentlemen and myself.

Energy apparently supplied in watts.		Work performed in watts.		Ratio of the energy apparently supplied to the real energy developed.	
Ganz and Co.	Westinghouse Co.	Ganz and Co.	Westinghouse Co.	Ganz and Co.	Westinghouse Co.
18,000	21,840	11,000	17,595	0·611	0·805
24,200	30,295	14,600	25,365	0·603	0·836
29,800	43,624	22,700	36,915	0·761	0·846
...	56,800	...	48,675	...	0·856
...	67,500	...	59,440	..	0·88
...	79,100	...	67,365	...	0·851

"If we compare these figures we will find that the most favourable ratio in Ganz and Co.'s motor is 0·761, whereas in the Westinghouse, for about the same load, it is 0·836, while in other instances, as may be seen, it is still more favourable. Notwithstanding this, the conditions of the test were not such as to warrant the best possible results.

"The factors upon which the apparent energy is mainly dependent could have been better determined by a proper construction of the motor and observance of certain conditions. In fact, with such a motor a current regulation may be obtained which, for all practical purposes, is as good as that of the direct-current motors, and the only disadvantage, if it be one, is that when the motor is running without load the apparent energy cannot be reduced quite as low as might be desirable. For instance, in the case of this motor the smallest amount of apparent energy was about 3,000 watts, which is certainly not very much for a machine capable of developing 90 horse-power of work ; besides, the amount could have been reduced very likely to 2,000 watts or less.

"On the other hand, these motors possess the beautiful feature of maintaining an absolutely constant speed no matter how the load may vary. This feature may be illustrated best by the following experiment performed with this motor. The motor was run empty, and a load of about 100 horse-power, far exceeding the normal load, was thrown on suddenly. Both armatures of the motor and generator were seen to stop for an instant, the belts slipping over the pulleys, whereupon both came up to the normal speed with the full load, not having been thrown out of synchronism. The experiment could be repeated any number of times. In some cases, the driving power being sufficient, I have been enabled to throw on a load exceeding eight to nine times that which the motor was designed to carry, without affecting the speed in the least.

"This will be easily understood from the manner in which the current regulation is effected. Assuming the motor to be running without any load, the poles of the armature and field have a certain relative position which is that of the highest self-induction or counter electromotive force. If the load be thrown on, the poles are made to recede ; the self-induction or counter electromotive force is thereby diminished and more current passed through the stationary or movable armature coils. This regulation is very different from that of a direct-current motor. In the latter the current is varied by the motor losing a certain number of revolutions in proportion to the load, and the regulation would be impossible if the speed would be maintained constant ; here the whole regulation is practically effected during a fraction of one revolution only. From this it is also apparent that it is a practical impossibility to throw such a motor out of synchronism, as the whole work must be done in an instant, it being evident that if the load is not sufficient to make a motor lose a fraction of the first revolution it will not be able to do so in the succeeding revolutions. As to the efficiency of these motors, it is perfectly practicable to obtain 94 to 95 per cent.

"The results above given were obtained on a three-wire system. The same motor has been started and operated on two wires in a variety of ways, and although it was not capable of performing quite as much work as on three wires, up to about 60 horse-power it gave results practically the same as those above mentioned. In fairness to the electricians of Ganz and Co., I must state here that the speed of this motor was higher than that used in their experiments, it being about 1,500. I cannot make due allowance for this difference, as the diameter of the armature and other particulars of the Ganz and Co. motor were not given.

"The motor tested had a weight of about 5,000lb. From this it will be seen that the performance even on two wires was quite equal to that of the best direct-current motors. The motor being of a synchronous type, it might be implied that it was not capable of starting. On the contrary, however, it had a considerable torque on the start and was capable of starting under fair load.

"In the article above referred to the assertion is made that the weight of such alternate-current motor for a given capacity is 'several times' larger than that of a direct-current motor. In answer to this I will state here that we have motors which with a weight of about 850lb. develop 10 horse-power with an efficiency of very nearly 90 per cent., and the spectacle of a direct-current motor weighing, say, 200 to 300lb. and performing the same work would be very gratifying for me to behold. The motor which I have just mentioned had no commutator or brushes of any kind, nor did it require any direct current.

"Finally, in order to refute various assertions made at random, principally in the foreign papers, I will take the liberty of calling to the attention of the critics the fact that since the discovery of the principle several types of motors have been perfected, and of entirely different characteristics, each suited for a special kind of work, so that while one may be preferable on account of its ideal simplicity another might be more efficient. It is evidently impossible to unite all imaginable advantages in one form, and it is equally unfair and unreasonable to judge all different forms according to a common standard. Which form of the existing moters is best time will show ; but even in the present state of the art we are enabled to satisfy any possible demand in practice."

THE LONDON COUNTY COUNCIL AND THE METROPOLITAN ELECTRIC LIGHTING SCHEMES.

The following is the letter addressed by the London County Council to the Board of Trade, in reply to their letter of the 18th May :—

"SIR: The Council has under consideration your letter of 13th March last, in which, referring to the electric lighting schemes of the present Session, you express the wish of the Board of Trade to be furnished with any observations which the Council may have to offer upon the large and very important question of the future of electric lighting in London, and you refer especially to two questions of principle which have arisen in relation to the matter, viz. :—(1) What should be the extent and nature of the area to be granted ? and (2) Should or should not concurrent powers be granted

Digitized by Google

to two or more companies within the same area? The Council has also considered the further letter from the Board of Trade, dated 18th of May, forwarding copies of a report by Major Marindin, R.E., on the result of his inquiry into the applications for Provisional Orders and Licenses under the Electric Lighting Acts, 1882 and 1888, as well as into the subject matter of the Bill introduced into the House of Commons by the Metropolitan Electric Supply Company.

"The Council has directed me to submit the following suggestions and observations for the consideration of the Board of Trade when dealing with the electric lighting schemes affecting the county of London.

"The Council agrees that extensive areas may properly be granted to companies when their financial and technical means of carrying out the powers entrusted to them are of a satisfactory character, and accepts generally the recommendations of the report as r gards the districts to be allotted to the several companies.

"The Council considers that in the interest of the public competition is desirable under proper restriction.

"The Council is not prepared to offer any opinion or suggestion with reference to the scientific or technical portion of the report, but desires to express its full concurrence with the recommendation in Major Marindin's Report that a company supplying a large area without a reserve of current should be required to provide duplicate sets of generating machinery in separate buildings and duplicate sets of mains, in order to secure a proper and continuous supply in case of a breakdown of machinery or other default; and, further, that every possible means should be taken for guarding against danger to the public from currents of high tension.

"The Council concurs in Major Marindin's suggestion (2) that certain streets should be scheduled in each district of the compulsory laying of mains, and that the supply in the remainder of the area should be made compulsory, upon requisition of consumers, on fair and reasonable conditions; and suggests that in case of such supply not being afforded after a sufficient interval of time, the Order should be revoked as regards the whole of the parish or district in which such default occurs. It appears to the Council that without such a provision being made a company might be in a position to supply those parts of a parish or district where there was a good demand, and to leave unsupplied those parts of the area in which the demand was limited. The Council further suggests that the companies should be required, in all streets where mains are laid, to bring the supply at their own cost to the consumers' premises.

"The Council concurs in the suggestion (6) in Major Marindin's report that wherever a company now supplying a district by means of overhead wires is granted an Order for such area the company should be placed under statutory obligation to remove these overhead wires; and the Council suggests that it should be an indispensable condition of the granting of any application for an Order or License that, in the area referred to therein, all wires and mains should be laid underground.

"With reference to Clause 55 of the London Company's Order, which would enable the company to supply electricity to a Vestry or District Board for the latter to retail to consumers, the Council considers the expediency of granting such a power to be doubtful, and would suggest that, if allowed, a provision should be inserted that the power given by the clause shall in no case be acted upon without the consent of the Council having been first obtained.

"The Council also submits the following general suggestions applicable to all the Orders and Licenses, namely:—

"(*a*) That the terms and conditions of all Orders or Licenses granted should be as nearly as possible identical.

"(*b*) That companies should be required not only to make use, with the consent of the Council, of subways now made, or which may hereafter be constructed, in streets where mains are to be laid, but to pay a fair rent for such use, and further, that in case of subways being in future made in streets where wires are already laid, the companies should be under an obligation to remove the wires into such subways and to pay a rent for the use of them, a reasonable time (say three years) free of rent being allowed as a set-off to the cost of such removal. That the power to make subways in the London streets should be vested in the Council, and not in the local authorities of the several districts.

"(*c*) That provision should be made to prevent the opening of any thoroughfare in the county of London for the purpose of laying mains, &c., until the consent in writing of the Council shall have been given to such opening.

"(*d*) That provision should be made for exempting the Council and the Vestries and District Boards from liability in respect of any damage which may be done to mains, &c., in carrying out works of repair or improvement in streets or roads, or from the use of steam rollers in the execution of such works.

with main or local sewers, or with the proper access to them, without the consent of the authorities in which such sewers are vested; and that plans of works which would interfere with sewers in any way should be submitted for the approval of such authorities before the works are begun.

"(*e*) That provision should be made for preventing interference

"(*f*) That, in view of future possible reduction in the cost of production which may be made as the result of experience and invention, there should be a provision that the maximum price of eightpence per Board of Trade unit proposed to be adopted shall be subject to revision at the end of seven years; and that in order to insure healthy competition between the companies during that period—(1) No amalgamation or working agreement between companies should be permitted without the consent of the Council, and (2) Power should be given to the Council, at the request of a Vestry or District Board, or on the requisition of inhabitants in any street or district, and with the consent of the company interested, to extend the area of such company to such street or district without the necessity of obtaining another Order. That clauses should be inserted providing for the application at the end of the seven years of a sliding scale of price and dividend, on the basis of a dividend of 8 per cent., leaving the initial price and arrangement of the scale to be determined at the expiration of the term of seven years.

"That the minimum charge for supply should be fixed as low as possible, and that should such minimum be fixed at £1 per quarter or over, it should be reckoned by the year and not by the quarter, because of the irregular requirements of the consumer at different seasons of the year.

"(*g*) That for the purposes of purchase by a public authority, any additions made to the area of supply of any company shall be taken to be part of the original area granted to such company, and that the powers over the additional area shall terminate at the same time as those over the original area, unless at the time the additional powers are granted to the company it shall be expressly stated to the contrary.

"The Council considers it would be to the advantage alike of the public and the companies that there should be one uniform system of regulation and control throughout the entire area of London. The necessity of this was forcibly illustrated by the very varied and in many respects inconsistent objections and requirements of the different Vestries and District Boards in regard to the proposed Orders, and by the complication and difficulty occasioned thereby. The Council is of opinion that, as the representative governing body of the whole of London, it should be appointed the controlling authority. It would always receive and give the fullest consideration to the representations of any local body on questions affecting its particular interests. It would remind the Board of Trade that the main roads throughout the Metropolis will shortly be under the jurisdiction of the Council, and should any general system of subways be hereafter resolved upon, such system will also be under its control. The Council considers also that it should be the authority to whom should be given the power of purchase in all cases at the expiration of the specified period; it would be manifestly impossible for any single Vestry or District Board to purchase a large undertaking supplying many parishes, such as that of the London or the Metropolitan Company. The Council would further suggest that if it is made the controlling authority it should be empowered to discharge the following duties, viz.:—

"Inspection of lines and works.

"Testing current.

"Testing and certifying meters.

"Taking proceedings for imposition of penalties or forfeiture in cases of default, as provided in the Order.

"And in order to carry out the work of testing, it should be made obligatory on the companies to provide and maintain sufficient testing stations and proper and efficient testing apparatus.

"The Council, in view of the fact that some companies have been, and are now, supplying electricity by overhead wires, without statutory powers, and being convinced of the undesirability of allowing this to be continued, would venture to suggest that in any further legislation on electric lighting the supply of electricity in any district, before obtaining statutory powers for such district, should be prohibited under penalty.

"The Council, in submitting the above suggestions, is animated by a desire to facilitate the working of the companies' undertakings in the various areas to be allotted to them, and, at the same time to insure that the interests of the public are properly guarded; and the Council thus submits its views in the full assurance that they will receive due consideration from the Board of Trade.

"Some of the Orders will affect the bridges, embankments, and other works under the jurisdiction of the Council, but the Council reserves any expression of opinion upon the manner in which its interests should be protected, as also upon other general matters of detail, until it shall have received the copy of the Model Order referred to in the letter from the Board of Trade on the 18th of May.

"I am, Sir, your obedient Servant,
"H. De la Hooke, Clerk of the Council.

"The Assistant Secretary, Railway Department,
"Board of Trade."

LEGAL INTELLIGENCE.

King, Brown and Co. *v.* The Anglo-American Brush Electric Light Corporation (Limited).

(Concluded from page 93.)

THE DEFENDERS' ARGUMENT.

On the termination of the case for the Pursuers on Thursday, the 23rd ult., the Argument for the Defenders was commenced, and did not conclude till Friday, the 24th.

Mr. JAMESON, in the absence in London of the Dean of Faculty, addressed the Court on behalf of the defenders. He said he should endeavour to follow as clearly as he could the order taken by his learned friend in his very clear and lucid speech, if he might be allowed to use that language.

LORD TRAYNER: I think it is highly deserved.

Mr. JAMESON said that of course he did not wish to say anything that might appear—

LORD TRAYNER: Patronising (laughter).

Mr. JAMESON: Yes. Mr. Murray had put the case in an order which he could not do better than follow, and also be more convenient for his lordship. The first question was about the commutators, and in regard to that matter it was, in the first place, necessary that they should clearly understand that that invention, so far as it related to the commutator, was not an invention of a new article. Commutators were known and used long before Brush. It was not a new application of electrical principles, nor was it a proper electrical invention at all. It was a pure invention in the mechanical appliance or form of commutator, and, as they submitted, an invention both of utility and novelty. Prof. Silvanus Thompson put it very well when he said, "They are claims for useful mechanical details and combinations of details." That commutator was exceedingly useful and novel. In the first place there was a large insulating hub—not a mere ebonite collar, as in the other case—between the metal of the shaft and the metal of the commutator, which had the result of effectually insulating every one of the wires from the shaft, and insulating them from one another. Then upon the top of that insulating hub they had sub-segments of a particular model. All these were brought in close electrical connections with the wires which came up under each of them and maintained the electrical connection. These were screwed firmly on to the hub, not being intended to be removed, and the screw was of a very peculiar form, which might be said to be all head. The result of that was that although some of the wires wore, there was always a head to keep the wearing segments on the sub-segments. In short, it had a head as long as there is any wearing segment to hold down. The head commenced immediately outside of the sub-segments. That was a very considerable advantage, because however far it was worn away, all that was done was to make a catch with a screwdriver and unscrew the screw. Taking the invention as a whole, he submitted that it was an invention of great utility and novelty. The learned counsel then proceeded at considerable length to deal with this part of the patent.

FRIDAY.

Mr. JAMESON resumed his argument on Friday. He maintained that Varley's commutator was not an anticipation of Brush's because the wearing segments were not detachably attached.

LORD TRAYNER: The case about the commutator stands thus. The Brush and the Varley commutators were quite common; the only question is, is the commutator described in your provisional specification, and as finally claimed—assuming it to be well known—mechanically as you put it or electrically as they put it, different from the commutator in use?

Mr. JAMESON said that of course he held it to be mechanically different.

LORD TRAYNER: But was yours mechanically different in such a way as to make it patentable?

Mr. JAMESON pointed out that there were the wearing pieces screwed on, and the wearing segments extending to and filling up the gap in the next ring, which were also the wearing segments of that ring; the cylindricity, the peculiar form of the screw, and the putting in of the screws from the outside so as to make them easily detachable; and the peculiar form of the hub. All these things would make it patentable.

He then turned to the more important question of the compound-winding. While it was true, as his learned friend had said, that possibly Brush no more than Varley—supposing Varley had any clear idea on the subject—knew what a valuable application was to be afterwards made of compound-winding, yet the specifications were totally different in one way. Brush, however, knew what he was about, because, although he was not seeking for what, strictly speaking, was known now as constant-potential, yet he was seeking a self-regulating machine, and he described it with admirable distinctness, and displayed it in drawings which "he who runs may read."

LORD TRAYNER: I do not know about "he who runs may read;" but I have looked at it a long time, and I cannot make much of it.

Mr. JAMESON said the provisions showed the compound-winding with a thick and a thin wire, and they also showed to a great extent the proportion and size of these wires. Brush had found that what he was really trying to get to was a machine which could adjust itself to varying loads, and could do so automatically. To do this it was necessary to have the mechanism of the magnet maintained at something like constant power, so that they might produce electricity sufficient to do their work. He might have thought more about currents than about potential, but be that as it might, his object certainly was to procure a machine which, as he said, would have the power constantly maintained. Every one of the witnesses admitted that constant potential was not a thing that could be the subject of a patent, nor could they obtain a patent for a machine which in all circumstances would give constant potential, because constant potential depended upon the work to be done, the speed at which it went, the way it was done, and a number of things of that sort. Now there could be no doubt that Brush's machine—and this was practically admitted by the pursuers' witnesses—did produce constant potential in certain cases.

LORD TRAYNER: There is no doubt Brush's machine is a very good one, and it has been very valuable, but the question is whether it was anticipated.

Mr. JAMESON said his Lordship had been invited to compare Varley's specification with Brush's as to the disclosure concerning which machine could be made upon the footing that neither of them knew, and that there was not in the specification set forth any object to be attained by a machine of this kind. Now that was not so. It was so with regard to Varley. Varley never made it one of his objects, and he did not claim it. Brush, on the other hand, set out with his object, not to obtain constant potential but to patent something that would lead to it—some machine giving data of a certain kind. His object was to get a self-regulating machine, and he described how that was to be done, and set out in drawings how he wished it to be carried out. Therefore, in comparing one sentence of Brush's specification with one of Varley's, they must keep in mind that Brush's specification was altogether occupied in describing a machine with magnets wound in this way for a particular object, while in Varley's specification there was no indication of what he was trying to get at, and there were lots of indications to a contrary effect. These indications were misleading, and would take a person away from the sense of the words of the specification, assuming he was trying to describe compound-winding. It would not do to refer for the purpose of comparison to the specification without showing that Varley's alleged anticipation of Brush referred to what Brush said in describing his machine. Brush had an object before him which he set forth and which he proposed to accomplish in a well-defined way, aided by drawings which he set out. Turning to Varley's specification of 1876, he referred to the lines on page 8—"Part of the electricity developed by the machine is diverted to maintain the magnetism of the magnets, and the remaining portion is used to produce the electric light." The diversion of the magnetism must be to one of two things—either to shunt or to separate excitation within the machine, such as they had in Wylde's machine and others. As Sir Wm. Thomson had said in his evidence, the statement "remaining portion was used to produce the electric light" meant that it was used only to produce electric light. That was a fair interpretation of the sentence in the specification as it stood.

LORD TRAYNER said the remaining portion might return for some purpose.

Mr. JAMESON held that there was no indication of that, and that an operative knowing nothing about the shunt—which was really unknown at that time—would naturally think only of what other methods were in vogue. Varley's statement that there were several well-known modes of using the remaining portion of the electricity answered exactly to what was accomplished by Wylde and others. He therefore submitted that an ordinary intelligent electrical workman at the date of Varley's patent would be most likely to suppose from this part of the specification that the electricity would be developed by the machine, and not obtained by bifurcation in the way the shunt-series operation was. Alternatively he submitted that taking this along with the rest of the specification there was really such a mass of incongruities that no workman would be led to wind a machine in this way or think of doing so. There was no well-known way of diverting the current by bifurcation. Shunt was not known in these days. It was so little known that Hadden claimed it in his specification. The well-known way of diverting the electricity referred to by Varley was not bifurcation at all, but by having a separate coil running round the magnet brought from a separate part of the machine. It was simply a portion of the machine-power cut off and sent straight to maintain the magnet while the rest of the electricity went the other way. Of course there could be no anticipation of compound-winding, even supposing there were two windings on the field magnet, for the one was series and the other was a winding led from a different part of the machine altogether. In support of his contention Mr. Jameson referred in detail to the evidence of Sir William Thomson, whose verdict on Varley's specification as a whole was that it did not disclose a series-shunt machine as described by Hadden, and that any electrical workman in 1876 reading Varley's specification would not have had disclosed to him a system of series-shunt winding. That was the deliberate opinion of probably the greatest electrician of the day, who had followed all the changes and improvements in electricity. This was of the very highest importance in this case, in which there was certainly a very heavy onus on the pursuers, for admittedly until Crompton's case there was no question of Brush having been the first person to disclose compound winding. Then Varley came forward with his specification, and said he disclosed this thing long ago.

LORD TRAYNER: There is always some point at which the question of an anticipation is brought forward.

Mr. JAMESON: Yes, but it is generally an early point.

LORD TRAYNER: Not until it is somebody's interest to fight it, such as King, Brown and Co.

Mr. JAMESON said that nobody ever heard of Varley's anticipation before Crompton's case. The extraordinary thing was that moving in electrical circles he never divulged or disclosed or claimed anything in connection with compound-winding until this case of Crompton's arose, and then he had some negotiations, after the thing was done, with the Brush Electric Light Company. Counsel did not lay much stress upon that, for no doubt Varley tried to make the best of his position. Some of the witnesses, other than Sir Wm. Thomson, said that the first two and a-half

Digitized by Google

lines of Varley's specification if they described any portion of the shunt machine described simple shunt and nothing more.

LORD TRAYNER: If anybody goes that length he goes a good way, because if these lines describe shunt they undoubtedly describe a system of bifurcation. Yet Prof. Silvanus Thompson says he cannot find any suggestion of bifurcation in these three lines at all.

Mr. JAMESON said that was because the idea at that time was excluded, for there was no bifurcation known at the time in that electrical world. Of course taking off the current was quite well known in telegraphy. Then another point Sir William Thomson made, and Prof. Silvanus Thompson and other witnesses agreed with, was that the idea of storing the magnetism was erroneous. They had good reason to believe from these things that Varley was not attempting to describe compound-winding. There were a great number of other absurdities in this specification.

LORD TRAYNER: Is it material how many absurdities there are if you find shunt-series described and disclosed? If you find series-shunt disclosed then these absurdities are of no moment.

Mr. JAMESON said that the series-shunt as described here was a part of the machine and nothing more, and it would never occur to a workman who took this specification as a whole to fix upon this as describing a new mode of winding.

LORD TRAYNER: The workman in whose hands the specification was put in 1876 made a machine which was of compound-winding.

Mr. JAMESON: Yes; but under Varley's instructions.

LORD TRAYNER: No doubt; but that showed that Varley knew what he was doing.

Mr. JAMESON said that if they were to believe that this machine was made expressly for this purpose it was compound-winding; but there was this observation to be made, that it was an experimental machine. It might be coupled up in many different ways, and had ten terminals.

LORD TRAYNER: Although it had ten terminals it was compound-winding all the same.

Mr. JAMESON: It had double winding, but it was not series-shunt.

LORD TRAYNER: In what other machine have you double winding—wires of different resistance?

Mr. JAMESON: I do not know of any.

LORD TRAYNER: You may have a machine with two coils of wire.

Mr. JAMESON: You may have them quite well on the principle of different excitation.

LORD TRAYNER: Let me see in the evidence anything that indicates that in a machine which was series, and had separate excitation within itself, that the coils of wire passing round the magnets were of different sizes.

Mr. JAMESON said he did not think there was such a thing in the evidence. A workman reading Varley's specification might quite well think there were good reasons for having that wire for the excitation of the magnets of less resistance. It might maintain the electricity longer or retain the residual electricity longer, and it might have a more permanent effect with currents passing at so many times. Curiously enough, what Cromwell Varley foreshadowed was a coil of wire closed in itself all round the magnet to detain a certain amount of electricity or magnetism in the coils in which it was wound. That was a case of two coils of different resistance. There was such a hazy notion of the thing in Varley's mind that he was not likely to describe it very clearly in the specification.

LORD TRAYNER: The question is whether you have in this hazy expression a point which struck at series-shunt by the use of two wires of separate resistance round some magnet, the principle of which was not known at the time but is known now.

Mr. JAMESON maintained that there was no disclosure of a purpose in Varley's specification. He appreciated the point about greater resistance, which showed there was in Varley's mind some notion of the kind; but the suggestion, although it seemed very important to people now, would not necessarily to a workman at that date suggest that the purpose of having greater or less resistance was that of self-regulation.

LORD TRAYNER: Would it not suggest something of the kind to a workman if he found two wires of greater or less resistance?

Mr. JAMESON: He would find so many absurd things in the specification that he would think it was another conundrum.

LORD TRAYNER: And, like the American, he would give it up (laughter). But there was Siebe and Gorman's machine.

Mr. JAMESON: They were partners with Varley.

LORD TRAYNER: That machine showed he knew what he wanted.

Mr. JAMESON: Yes; he had a notion in his head about it.

LORD TRAYNER: If that lamp was used on Varley's machine it must have been in series-shunt. The only time it was used was in connection with the lamp, and therefore the only time it was used was as series-shunt.

Mr. JAMESON: I doubt if it was.

LORD TRAYNER: When it was used it was used with the lamp. Your own evidence shows that it must have been used as series-shunt.

Mr. JAMESON: It might have been used in the series without shunt coupling. There is one thing certain, that the use was so unsatisfactory that they dropped it.

LORD TRAYNER: Of course, Mr. Jameson, although my observations appear to be adverse to you they are simply made for the purpose of obtaining information. I have no opinion in the case the one way or the other.

Mr. JAMESON proceeded to say that it was proved that when the lamp was out it attracted keys and other things. That would be accounted for by the residual magnetism. There was nothing to show that at the time the lamp was there it was not coupled up so as to produce the magnetism of the magnets by a separate excitation arrangement. Throughout the whole specification Varley was trying to show how his great idea of these bobbins split up into groups could be applied. The same arrangement would take place with regard to the storing up of the electricity which he claimed as his invention. As pointed out by Sir Wm. Thomson, Prof. Silvanus Thompson, and Prof. Perry, his specification was full of inconsistencies. It was founded on an erroneous idea, and was in practice a complete failure, the lamp never having been put in use. Even supposing that Varley made his machine in series-shunt, and intended coupling it up in that way, that of course would be no disclosure of series-shunt so far as the specification was concerned unless in the specification he put the public in as good a position as he himself was in with regard to information. As to the models which the four witnesses for the pursuer said they made from Varley's specification, he contended that they would have required to know how much these witnesses had heard about electricity. Immense progress had been made since 1876 in electricity, and it was impossible to judge between these witnesses and the workmen of thirteen years ago.

LORD TRAYNER: If you take the evidence as true the two lads who were examined had no information of any special kind, and yet from the specification they made these models, which were said by your witnesses to represent series-shunt winding.

Mr. JAMESON proceeded to point out that Varley's machine was proved to be merely an experimental machine, and he referred his Lordship to several cases to show that if a machine was made and used merely experimentally and then thrown aside and not used that would not be held to be anticipation of another machine that was brought forward. He maintained that it could not for a moment be held that, for purposes of practical utility, Varley's patent had anticipated that of Brush.

LORD TRAYNER: There is also this difference in your favour, that whatever Varley's purpose was in mentioning double-winding he made no claim for it.

Mr. JAMESON: That is a very important point.

LORD TRAYNER: But the question is whether Varley described in his specification and had in view such a machine as would, if money had been expended on it, and it had been put into the market, have done just what Brush's machine is doing now.

Mr. JAMESON: I can say nothing further on that point than this, that after fair and sufficient trial, after being exhibited to people interested in the matter, and a deal of money having been expended on it, the machine was not taken up as being a success.

Mr. JAMESON proceeded to argue that the fact of Varley's machine having been thrown aside until it was disinterred for the Crompton case was a very strong presumption that it was a merely experimental machine. He maintained that the Brush commutator was an important mechanical improvement, and that it was sufficiently disclosed in the provisional specification. Varley's patent did not disclose compound-winding necessarily at all; but whether that was so or not, it did not disclose it in such a way as to constitute an anticipation of Brush's patent, which described compound-winding much more lucidly and with much greater detail for the instruction of workmen. With regard to the use of Varley's machine, he held that it was just experimental, and the best test of that was that it had never been heard of since. It was quite against the policy of the patent law, and of the authorities which he had quoted to his Lordship, to hold that such a machine could constitute a public use so as to invalidate a subsequent patent.

LORD TRAYNER: I am extremely obliged to you, Mr. Jameson, for your very able argument, which has made a great impression on my mind.

His LORDSHIP then took the case to avizandum.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, June 7th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Recent Researches into the Origin and Age of the Highlands of Scotland and the West of Ireland." By ARCHIBALD GEIKIE, F.R.S.

SATURDAY, June 8th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Idealism and Experience in Philosophy and Literature." By Prof. W. KNIGHT, LL.D.

PHYSICAL SOCIETY.

3 p.m. "On a Method of Suppressing Sparking in Electric Currents." By Prof. S. P. THOMPSON, D.Sc. "On a Shunt Transformer." By Mr. E. W. SMITH. Notes on Geometrical Optics:—(1) "On the Deduction of the Elementary Theory of Mirrors and Lenses from Wave Principles." (2) "On a Dioptic Spherometer." (3) "On the Formula of the Lenticular Mirror." (4) "On the Use of the Focal Circle in Mirror and Lens Problems." By Prof. S. P. THOMPSON, D.Sc. "On the Use of the Biquartz." By A. W. WARD.

TUESDAY, June 11th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Some Recent Biological Discoveries." By Prof. E. RAY LANKESTER, M.A., F.R.S.

WEDNESDAY, June 12th.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. "Description of a New Species of Megalotrocha from Brisbane." By V. Gimson Thorpe, R.N.

THURSDAY, June 13th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture "Chemical Affinity." By Prof. DEWAR, M.A. F.R.S.

The Electrician.

ublished every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

A PROFESSORIAL ATTACK UPON THE BOARD OF TRADE REPORT.

Prof. SILVANUS THOMPSON has written to *The Times* a letter expressing feelings of "astonishment and regret" at the issue of the Board of Trade Inquiry. Prof. THOMPSON feels that "conclusions so illogical, so obviously one-sided, and so inimical to the interests of a large section of the community" are indeed to be deplored.

Inasmuch as this view of the matter differs somewhat widely from that to which we have already given expression, we have felt it desirable to again go over the grounds upon which our first impression was based. Having done this, as we trust, with due candour, we venture now to say that there is no such occasion for alarm and dismay as the learned Professor would have us believe, whilst at the same time we feel indebted to Prof. THOMPSON for giving us a suitable opportunity to call attention to some features of the report which are of great importance to the industry at large.

Let us first see what are the grounds on which we are called upon to pronounce Major MARINDIN'S proposals "illogical, lame, and unfair," and to join with Prof. THOMPSON in implor-

Digitized by Google

ing the London County Council to refuse their august sanction to the scheme. The gist of Prof. THOMPSON's complaint may be gathered from the following sentences, which we bring together from different paragraphs of his letter:—

(1.) "Is it fair or right that in the only districts where absolute monopolies are granted they should be granted to alternate-current systems? . . ."

(2.) "Does it not seem monstrous that the whole of the proposals of the Electric Power Storage Company, one of the competing applicants, who asked not for a monopoly for themselves, but for fair field to compete with the alternating-current companies, should by the Board of Trade's action be ruled out on a mere technicality, which could have been set right at Somerset House for a few half-crowns?"

(3.) The third ground of indictment is that "Mr. CALCRAFT seems tacitly to have adopted the notorious [why notorious?] creed of the London Electric Supply Company . . . . and in so doing he not merely abandons, but deliberately inverts, the sound principle laid down in his own report, in 1883, that so long as a company in a district does its duty to the public, so long a competitor is not to be admitted."

Let us consider these objections in order. In the first it is implicitly stated that in certain districts an "absolute monopoly" has been conferred, and that in every such case it is an alternate-current system which has thus been favoured. We must, however, be permitted to express some genuine surprise that so acute and careful a critic as Prof. THOMPSON should have been led to overstate his case in so glaring a manner. Surely it is evident enough that the very ruling which furnishes ground for one of his complaints renders it untrue to say that any "absolute monopoly" has been conferred on any one. The examples which have just been afforded in the case of the Chelsea Order and the St. James' License are sufficient to show that on due cause being alleged the Board will at any time lend their ear to any suitable applicant for powers within the districts which may happen for the time being to rest in the hands of any single Company. "Absolute monopoly" has been ruled out of existence. It is, however, still more to the point to observe that (with the exception referred to in the second of the grievances enumerated above, and with which we shall presently deal) in the territories where alternate-current companies hold for the present undivided sway no one else has so far sought to share their responsibility. In the City, in Clerkenwell, in Holborn, in Bloomsbury, in Southwark, Lambeth, Bermondsey, and Rotherhithe there were no other applicants. To find fault with Major MARINDIN on this score is, therefore, so far as these districts are concerned, simply absurd.

There remains, however, the important district of the Strand, and here we come upon the next clause of the indictment. In this quarter the applications, both of the London Electric Supply and of the Electrical Power Storage Company, were refused in favour of the Metropolitan. The London Company has obtained ample compensation elsewhere, but the Electrical Power Storage Company has lost its entire case. If it were true, as Prof. THOMPSON alleges—we would rather say, if it were the *whole* truth—that this decision is based upon a "mere technicality" relating to the form in which the Company had first been registered, then, although we could not admit that the edict was properly characterised as "monstrous," we might easily think it needlessly stringent. But what are the facts? Referring to the report (*The Electrician*, May 24, p. 59), we shall find that in spite of Prof. THOMPSON's indignation the INSPECTOR carefully abstained from any definite pronouncement upon the point now in question. His decision was based upon a question of principle of far higher importance than this. "*However this may be*," is the language of the report (and it is of such importance that we transcribe the passage at length), "it is perfectly clear from the evidence of the Manager of the Company that the Company does not intend to exercise the powers which would be granted by the Order, but to transfer them to some other persons. I have no doubt that these persons are perfectly willing and competent to carry out the powers and obligations of the Order, but I submit that it would be quite contrary to practice to grant an Order to any but a properly-constituted company, proved to be in a position to act under it; and as this has not been done I cannot recommend that the Order be granted."

It will thus be seen that had Major MARINDIN reported in favour of this application he would virtually have thrown open the door to a class of speculation which most of our readers will admit to be extremely undesirable. As to the *bonâ fides* of the Electrical Power Storage Company in this instance probably no one entertains the slightest doubt, and we may offer them sincere condolence upon the unfortunate issue; but that they were ill-advised to make application in such form, and that it is for the good of the community at large that such application should have been refused, we think equally evident.

With regard to the third clause of Prof. THOMPSON's indictment, in which he deals with the question of monopoly, we have always admitted that much may be said on either side. In this particular case it has been already pointed out that the decision arrived at cuts the ground from under the feet of the first of Prof. THOMPSON's protests; and hence we are entitled to argue, if we care to do so, that he is not in a position to maintain his charge of inconsistency against the Board of Trade. It is, however, more to the point to observe that the vast extension of the long-distance transmission of electrical energy has greatly altered the aspect of the problem within the last few years, and upon the whole it seems to us that the conditions of a fair field and no favour are best secured all round by the arrangement now sanctioned. We confess, however, that we were a little surprised to learn from Sir MICHAEL HICKS-BEACH in the House of Commons that any other view would have been contrary to "the clauses" of the Act of 1883. We venture to think that the President of the Board of Trade would have been considerably puzzled had he been asked to quote the clause to which he referred.

THE POSTMASTER-GENERAL AND THE TELEPHONE COMPANIES.

In the letter which the POSTMASTER-GENERAL found it necessary to address to the Telephone Companies on the very day upon which the amalgamation scheme received the sanction of their shareholders, he states that "whether such a course (namely, the amalgamation scheme) can be legally adopted under the terms of the Licenses granted by the Post Office is a question on which the POSTMASTER-GENERAL does not at present offer an opinion." We venture, with due deference, to submit that it is high time that the exact legal position of the Telephone Companies in this matter was definitely established. It seems to us equally detrimental to the public interest and to the dignity of the POSTMASTER-GENERAL himself that this important point should remain in such obscurity and doubt. It is, of course, possible that Mr. RAIKES has already satisfied himself as to the exact limit of the powers which have been conceded to the Companies, but that he is uncertain as to how far public opinion is likely to support the department in any positively hostile action which might be taken. This is perhaps the more probable alternative, especially

Digitized by Google

in view of the fact that in reply to a question put to him in the House of Commons the same evening Mr. RAIKES remarked that he was not at all sorry that the question had been asked, because "he thought it might serve to attract attention to a matter upon which an expression of public opinion might assist the department in protecting the public interest." From the point of view of public polity the whole matter may be summed up in the inquiry: What is the public interest? Is it to the public interest to allow long-distance telephony to compete with the Postal Telegraph service on fairly level terms, or should advantage be taken of the decision of 1880, by which telephony was declared to be a department of Telegraphy, and hence to come within the monopoly of the Postmaster-General?

It is not our present intention to offer a dogmatic opinion upon the points under discussion; we would prefer for the present to echo the wish of the POSTMASTER-GENERAL that public opinion should be attracted to the question. There can be little doubt that in certain more thickly populated districts of the country inter-urban telephony has already obtained so firm a hold that public opinion would vehemently oppose its extinction, or even any serious curtailment of the facilities at present afforded for its development. On the other hand, it will readily be conceded that the question of forming a telephonic network throughout the length and breadth of the country stands upon a very different footing. From the technical and commercial point of view we think it in the highest degree problematical whether any such system could possibly be made to pay its way; that, however, is at present a question for the Companies; and if they think they see their way to its successful solution, the public will have to consider whether or not it should support the POSTMASTER-GENERAL if he decide to prohibit the experiment.

One other point must not be overlooked. By the conversion of their shares at market value the Companies are effecting an apparent increase in the amount of capital invested in their undertakings. It is both natural and right that the POSTMASTER-GENERAL, in view of the early expiry of the patents and the possibility of a departmental purchase, should inquire narrowly into the effect which such a proceeding may be expected to have. His letter may probably be taken as a warning that in the case of any compulsory transfer the present transaction may to this extent be disregarded.

THE AMALGAMATION OF THE TELEPHONE COMPANIES.

In connection with the amalgamation of the United, National, and Lancashire Telephone Companies the Secretary to the Post Office has addressed the following letter to the Secretary of the United Telephone Company:—

"General Post Office, June 4, 1889.

"SIR: The Postmaster-General has had his attention called to the notice issued by the United Telephone Company to its shareholders on the 24th ultimo, and to the course which the Telephone Companies propose to pursue with the view to an amalgamation.

"Whether such course can be legally adopted under the terms of the Licenses granted by the Post Office is a question on which the Postmaster-General does not at present offer an opinion; but he desires me to acquaint you, for the information of the directors and shareholders of the United Telephone Company, that the amalgamation of the companies was not contemplated when the Licenses were issued, and that any assurance, outside the Licenses, which the companies may conceive themselves to have received from the then Postmaster-General cannot be regarded as applicable to the state of things likely to result from the proposed amalgamation.—Yours, &c., (Signed) "S. ARTHUR BLACKWOOD."

On Tuesday evening, in the House of Commons, Mr. R. Chamberlain asked the Postmaster-General if his attention had been called to the tactics by which the financial group now commanding the telephone system of the kingdom had met his refusal to grant a License to the amalgamated company originally projected; whether his attention had been directed to the amount of capital to be created under the new scheme, and to the high charges to the public that would have to be maintained in consequence, and to the proportionately enhanced price that would be demanded should the nation ever decide to purchase; and whether, under these circumstances, he would at once avail himself of the right reserved under the agreement with the Telephone Companies, and "establish, extend, maintain, and work" a telephone system such as would gradually bring the advantages of this invention within reach of the masses of the people? Mr. Raikes said he was aware of the proceedings of the Telephone Companies. The whole question of the telephonic services of the country was engaging his serious attention. He was not at all sorry the question had been asked, because he thought it might serve to direct public notice to a matter upon which expressions of public opinion might assist the department in protecting the public interest.

ALTERNATE-CURRENT WORKING.*

BY W. M. MORDEY.

(Concluded from page 98.)

SAFETY AND SAFEGUARDS.

I take this opportunity of bringing up this question, not because I have anything new to say with regard to it, but in order, if possible, to bring it a little nearer to a rational settlement.

It will be acknowledged that the first duty of an "undertaker" using high tension is to provide for the complete and absolute safety of the consumers. If there are no means of doing this, then the system is fundamentally bad, and must sooner or later be abandoned.

There are several ways of protecting the house mains more or less completely. I only need allude to three typical plans, all of which have already been discussed before this Institution.

One is the plan introduced by Mr. Kent, of entirely separating the primary and secondary conductors in a transformer by a sheet or division of earth-connected metal. This is open to adverse criticism on some points, but, on the whole, it is an effective plan.

Another arrangement is the ingenious one of Capt. Cardew, consisting of a sort of static mouse-trap, which immediately goes off when an unauthorised P.D. enters it.

The third plan is that of earthing the secondary, and it would be very instructive if those who so strongly oppose this plan would state just one real objection to it. It is a perfectly sure method, and costs nothing.

It renders it absolutely impossible for the consumer to get a dangerous shock under any possible combination of circumstances whatever.

The faults that may occur are—

(*a*) Contact between primary main or mains and earth.

(*b*) Contact between primary and secondary in a transformer.

(*c*) Contact between a person and a portion of the secondary conductor.

(*d*) Contact between that person and earth.

Now if all these contacts occur at the same time the "person" will get a shock.

But if the secondary is earthed no shock can be obtained, except, perhaps, a slight one due to the secondary P.D.

This simple plan has been approved by almost everybody, but it is received with opposition on the part of some of the fire insurance offices and others.

It is difficult to ascertain where the supposed danger is. If the secondary is earthed, the effect of a contact between primary and secondary, when the former is accidentally leaky, is at once to blow out the primary safety fuse of the transformer, and so cut out the offending house. This is the simplest and the best course to take, and prevents the continuance on the circuit of transformers that contain faults.

The Brush Corporation has adopted this plan with perfect success on a large installation abroad, and intends adhering to it where local circumstances permit.

It is to be remarked that it is not open to the objection that has been stated against earthing of one of the primary conductors, viz., that the telephones may be affected, for it is not permanent. The moment a contact occurs that could lead to a disturbance of the telephones the fuse prevents that disturbance being continued.

While effectually removing life risks this precaution does not increase fire risks; in fact, it tends to greater safety, as it is some sort of check on the character of the house-wiring work, and so reduces chances of faults such as short-circuiting of the secondary.

The rupture of a primary safety fuse is not a serious matter, and

* Paper read before the Institution of Electrical Engineers on Thursday evening, May 23, 1889.

Digitized by Google

in any case it is only what takes place under ordinary circumstances when any fault occurs that results in an excess of current.

As to static effects, I think it will be found that there will always be enough general leakage to prevent such effects being a cause of difficulty, even if the secondary circuits are not earthed.

Hysteresis and Eddy Currents.

Some explanation is necessary by way of preface to this section of the Paper. The experiments described were made with a direct-current dynamo, and on that account they only touch the fringe of this division of the subject. As I had no suitable alternator I was unable to pursue the question as far as I wished to do, but I hope I need make no apology for bringing forward such results as I have been able to arrive at.

As far as I am aware, no simple or practical method is known by which the power absorbed in eddy currents can be determined and separated from that due to hysteresis in the armatures of dynamos. This is a point of some importance, both as regards alternators and direct-current machines, for many reasons, one of the principal being that in the absence of exact knowledge on these matters it is difficult or impossible to determine to what extent the lamination of the iron cores should be carried. There are wide differences in the practice of the various designers and makers of dynamos in the thickness of the iron used.

Lamination may be carried to such a degree of fineness for the purpose of reducing eddy currents as to add very materially to the cost of production, the iron increasing rapidly in price as the thickness is reduced; and it may be that the point is sometimes passed beyond which no gain in efficiency is obtained. This is a question we wish to be enabled to settle.

Until Prof. Ewing* and Dr. J. Hopkinson† read their Royal Society Papers on the subject, very little was known of the heating effect of changes of magnetism. Prof. Ewing opens the part of his Paper dealing with this matter in the following terms (p. 552, *Phil. Trans.*):—

"The energy expended in a cyclic process of magnetisation can take no other form than that of heat diffused throughout the substance of the metal. Experiments have been made by Joule and others to determine by direct observation the heating effect of magnetisation in iron.‡

"In most direct measurements of this quantity no distinction is made between the heating effect due to the induction of electric currents and that due to changes of magnetisation *per se*; and so excellent an authority as Prof. Rowland, writing in 1881, has expressed himself as doubtful whether changes of magnetisation, considered apart from the currents they induce, give rise to any development of heat at all."

Further on, Prof. Ewing, referring to the dissipation of energy by hysteresis, which he had determined by laboratory experiments, says (*Phil. Trans.*, pp. 553, 554):—

"These developments of heat are so small as to make it apparent that the very considerable thermal effects which reversals of magnetism cause in the revolving cores of some dynamo-electric machines must be due almost wholly to the internal induction of currents, so far as they are not due directly to the current circulating in the coils of the armature.

"The experiments have a practical value in showing that cores which are so thoroughly laminated as to render the induction of currents within them unimportant do not involve any serious loss of energy, and that the efficiency of a machine with a soft iron core or cores whose magnetism is periodically reversed need not, on that account, be materially less than that of a machine which has no such cores. The absence of iron from the armature has been claimed, on the score of efficiency, as an important advantage possessed by some types of machine, but unless the claim has some other basis it appears to me to be illusory. Magnetic reversal does involve some loss of energy, but if the cores are properly laminated it is so small as to be practically insignificant."

I quote these passages as showing the position of the question. Prof. Ewing and Dr. Hopkinson give laboratory determinations of the magnetic loss in iron with various inductions and under various condition. It is, however, left somewhat in doubt as to whether the loss in dynamo armatures will be the same as in the laboratory experiments, the conditions being very different in the two cases.

On this point Prof. Ewing shows that hysteresis is much less when the iron is in a state of mechanical vibration than when it is in a state of rest, and states that in a dynamo the loss will be less than the experiments on still metal might lead us to expect.

Another way in which the dynamo conditions may cause some difference is the possible variations of the magnetic density that may exist in the core. Such variation may be considerable in armatures of large size.

Dr. Hopkinson (*Phil. Trans.*, p. 467) takes the magnetic loss in armatures as being the same as in the small pieces of iron tested by his method, and gives an example calculated for an armature core "finely divided, to avoid local electric currents."

It is to be noted, then, that both these authorities regarded eddy currents as unimportant in laminated armatures; but in the later Paper on "Dynamo-electric Machinery"* Drs. J. and E. Hopkinson published their famous investigation into the efficiency of dynamos, and gave very full particulars, from a study of which it is possible to ascertain the loss in eddies, on the assumption that the method of calculating the magnetic loss is correct when applied to armatures—a point which Dr. Hopkinson was not able to decide positively; but by assuming that it is applicable, then, by subtracting the calculated hysteresis loss from the ascertained total power unaccounted for, the eddy current loss is obtained, and as this process gives the hysteresis as accounting for only about 40 per cent. of the total loss in the armature core, it shows that the eddies could not by any means be considered unimportant, although the lamination was carried out to the extent of making the iron about 0·02 inch thick.

I now wish to describe a method by which the amount of loss due to each of the two causes may be ascertained experimentally in the workshop on a practical scale. It is a very simple one, although not, perhaps, capable in all cases of the highest scientific accuracy.

(*a.*) First run the dynamo on open circuit at various speeds (two readings will suffice), with the fields unexcited, or, better still, entirely absent, and measure the power absorbed in friction. Plot this value to any suitable scale, as O M in Fig. 3, the ordinates representing horse-power, while the abscissæ represent revolutions per minute.

In the figure the mechanical friction, being a quantity with which in this investigation we are not directly concerned, is plotted below the base line O M', in order that the other losses may be more clearly seen.

(*b.*) Next run again on open armature circuit with the brushes removed and the field normally excited, and measure the power absorbed. This will be the total power dissipated in friction, hysteresis, and eddy currents, if any, and must be plotted as O N. Then the ordinates lying between O N and O M' represent the sum of the losses due to hysteresis and eddy currents, and somewhere between O M' and O N must lie a line O P, separating the hysteresis from the eddy-currents.

We desire to find the position of this line. The difference between the rate of increase of the electric and magnetic losses enables us to separate them from each other. It may be taken that, with any given constant excitation, the loss from hysteresis is directly proportional to speed, within certain limits to be hereafter stated. The resistance (that of the iron) being constant, the eddy currents must vary as the first power of the speed, and the loss therefrom as the square of the speed.†

It will now be seen that it is easy to separate the values which are directly proportional from those which are proportional to the square of the speed.

Prof. S. P. Thompson, to whom I submitted this method, has kindly given me the following concise formulæ for finding the quantities:—

P and P_1 are respectively the combined magnetic and electric losses at the speeds S and S_1.

k = magnetic loss;
k_1 = electric loss.

$$k = \frac{P_1 S^2 - P S_1^2}{S^2 S_1 - S S_1^2};$$

$$k_1 = \frac{P S_1 - P_1 S}{S^2 S_1 - S S_1^2}.$$

Then, at any speed n,

Hysteresis $= k n$;
Eddies $= k_1 n^2$.

If armature cores are run in an excited field before winding, it can be determined to what extent their lamination is satisfactory and whether the iron is of good quality; and then, after winding the armature conductors, another test shows what the additional increase in the loss is, and separates the effects of eddy currents in the core from those in the conductor, and the hysteresis from both. The method may also be useful to investigate the losses in the cores of armatures of different types or differently built up, as, for instance, with iron wire or iron sheets.

This method has a useful application in rendering it possible to separate not only the magnetic loss from the electric loss in the iron, but to determine the waste by eddies in the copper winding of armatures.

It is usually entirely a matter of opinion as to how much of the power absorbed in running an armature on open circuit is due to any of the various causes referred to; and now that it is customary to wind armatures with heavy conductors, it becomes very desirable to be able to find in any particular case what proportion of the loss is in the copper and what in the iron.

In Fig. 3 are shown some results obtained with a four-pole (direct-current) Victoria dynamo run at various speeds up to 1,200 revolutions per minute, with constant excitation. Power readings were taken by means of a White's transmission dynamometer, constructed by the Brush Corporation for the purpose of testing dynamos; and the horse-power absorbed in mechanical friction in dynamo, belt, and dynamometer was subtracted from the power spent electrically and magnetically.

To reduce errors in the dynamometer readings the dynamo was fitted with two pulleys, one twice the diameter of the other. This allowed of the dynamometer being run at the same speed, while two different speeds of the dynamo were obtained by changing the belt from one pulley to the other. Readings were taken at four speeds, viz., 450, 600, 900, and 1,200 revolutions per minute, corresponding to 15, 20, 30, and 40 ∿ per second. The position of O P was readily found by "trial and error," this being a shorter process for a concrete instance than the application of the general

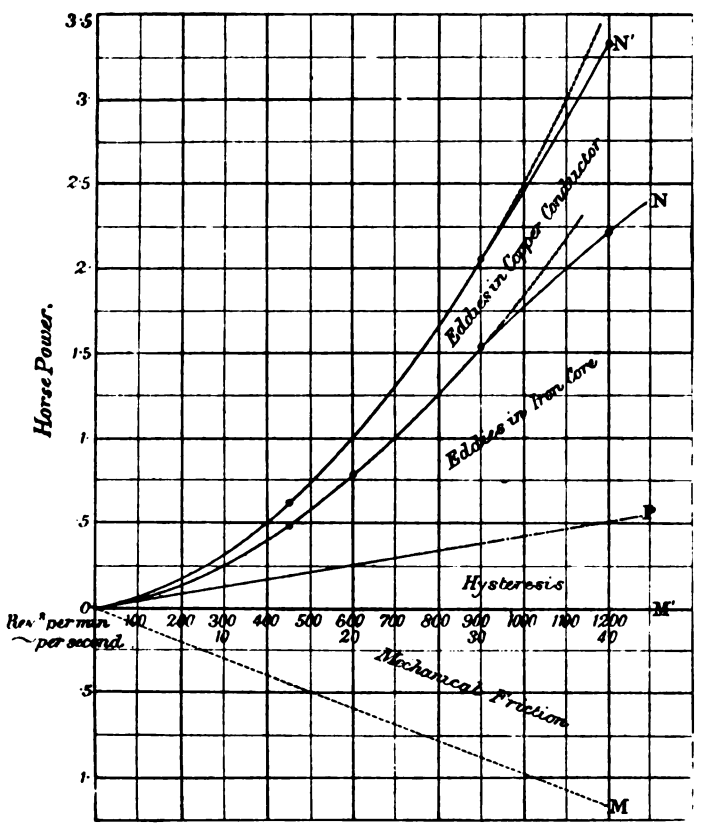

Fig. 3.—Determination of Losses in Dynamo Armature.

formulæ. The assumption on which this method of testing is based was found to be correct up to 900 revolutions. The reading at the higher speed of 1,200 revolutions, or 40 ∿, shows that disturbing influences began to affect the results by reducing the rate of increase of the losses. The continuation of the curve O N in a full line shows the actual loss, while the continuation in a dotted line, which is a parabola on O P as an abscissa, shows what the loss would be if the rate of increase holding for low speeds were maintained.

This shows that this method is perfectly applicable to ordinary direct-current machines—for instance, to two-pole dynamos up to 1,800 revolutions per minute, or 30 ∿ per second—but that it is less useful for alternators.

The disturbing causes are probably rather complicated. They may be due partly to self-induction in the circuits of the eddy currents, to lower magnetisation (although this effect, if present, is very slight, as was shown by the E.M.F. being almost perfectly proportional to speed), and to vibration. "Viscous hysteresis," if it exists, will raise the magnetic loss. There may be such an effect, in spite of the lowering of the curve, but it cannot be recognised, on account of the unknown variation of the eddies, at the higher speed. Iron-cored alternators working at high periodicities may be tested in the following way, which will give some approach to correct results:—Let the test be taken at a low speed (not more than 30 ∿. This will give the hysteresis per period and the eddies at that speed. Then, if at any higher speed the E.M.F. is proportional to speed, it may be assumed that the magnetic induction is the same as before, and the hysteresis per period will at any rate not be less than at the lower speed. It may be more. The difference between the calculated hysteresis, O P, and the ascertained total loss, O N, will be the eddies; or, if viscous hysteresis is a fact, it will be extra loss due to viscosity plus that due to eddies.

Heating of the armature core, and consequent increase of the resistance of the iron, is not responsible for the bending down of the curve O N in Fig. 3 (although it would have that effect under ordinary circumstances), as the experiments did not occupy sufficient time to allow of any sensible rise of temperature. The effect is probably very complex and obscure, but it is one that well deserves study on account of its present industrial importance.

It should be stated that the dissipation of energy (which has been spoken of as being in the armature) may be partly in the field magnets. This was, however, not the case in the experiments referred to. The conditions necessary for the prevention or reduction of eddies in the iron of field magnets are now pretty generally understood,* but it should be observed that it is not by any means as easy to check such waste in alternators as in ordinary dynamos. It is both better and easier to prevent than to cure them.

If a good transmission dynamometer is not available, results almost or perhaps quite as good may be obtained by running the machine at various speeds by means of an electric motor, and measuring the power required by the motor—first with the fields of the machine unexcited, to get the mechanical friction, and then with the fields excited, to get the total loss. The motor should then be run alone, to find what is absorbed in driving it at various speeds. The increase in watts over these last values, with the internal losses in the motor conductors calculated out and subtracted, will give, with a very fair degree of accuracy, the energy dissipated in the machine under test.

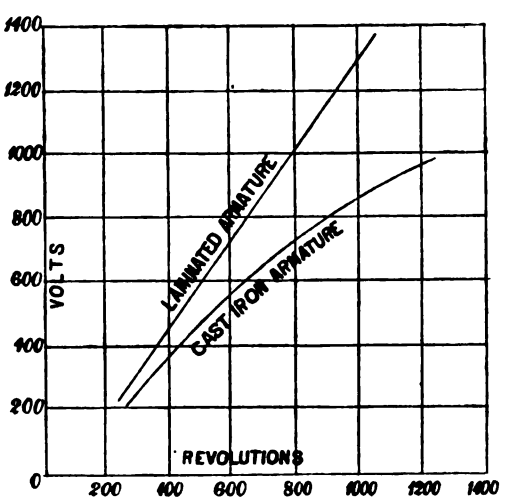

Fig. 4.

The upper curve, O N', was plotted from readings taken after the armature was wound, and the difference in the ordinates between O N and O N' shows the eddy current loss in the copper conductor at various speeds. This loss, like that of the eddy currents in the iron, rises as the square of the speed up to 900 revolutions, or 30 ∿, above which it rises rather less quickly. The full line O N shows the actual loss, the dotted line above it showing what it would be if the rate of increase were maintained. The difference is no doubt due to self-induction.

That the effect of self-induction is not noticeable unless the eddy currents are considerable is in accordance with experiments that I published some years ago in connection with the Brush dynamo.† The results then obtained are shown in Fig. 4. The straight line connects speed and the potential difference at the terminals with the laminated armature; the lower and slightly curved line shows the potential difference with the old form of cast-iron armature, which had only coarse divisions, scarcely meriting the term "lamination." The curve shows that the E.M.F. rose less quickly than the speed on account of the serious generation of eddy-currents.

* See numerous practical notes on this subject scattered through Prof. Thompson's "Dynamo-Electric Machinery."

† *The Electrician*, October 2nd, 1885.

Digitized by Google

In the laminated armature, although, of course, there were still eddies, their effect was not sufficient to cause any bending down of the E.M.F. line at any practicable speed of driving.

Coming now to an examination of the results obtained in the experiments, and shown in Fig. 3, we see that the hysteresis loss in this particular dynamo—which I should mention is capable of working continuously with a normal load of 18,000 watts—was 0·195 horse-power at 450 revolutions, and 0·39 horse-power at 900 revolutions, the latter corresponding to 30 ∿ per second.

The magnetisation* was about 12,300 C.-G.-S. lines—not by any means a high density. The armature had a ring core, nearly square in cross-section, of 12 square inch area, and contained 615 cubic inch, or 10,086 cubic centimetres of iron strip 0·012in. thick (No. 30 B.W.G.) separated by paper. This is a degree of lamination beyond which it is inconvenient to go. The peripheral portion was wound with this iron in parallel bands ½in. wide, in order to reduce eddies caused by lines entering the periphery. The main inner portion of the core was of wider strip.

We find from the figures that the loss in hysteresis at 900 revolutions was as follows :—

0·39 horse-power = 291 watts = 0·473 watts per cubic inch, or 0·029 watts per cubic centimetre. As the periodicity was 30, the 9,613 ergs, or of energy per complete period per cubic centimetre was dissipation 0·001 watts nearly.

It is interesting to compare this result, obtained in what may seem a rather crude manner, with the values given in the Papers referred to. Prof. Ewing says (*Phil. Trans.*, p. 553) ". . . the double reversal of a strong condition of magnetism in soft iron involves the expenditure of about 10,000 ergs per cubic centimetre." He gives the energy as 9,300 ergs, with a magnetisation of 13,190 in very soft annealed iron. Dr. Hopkinson gives 13,356 ergs, with a magnetisation of 18,250.

Much of course depends upon the quality and hardness of the iron, but my results come out very close to those of Prof. Ewing and Dr. Hopkinson. This may be taken as proving the method capable of considerable accuracy. The eddies in the iron, it will be seen, are by no means to be neglected, even with the very fine subdivision that was used.

The eddies in the conductor are rather greater than usual, as the armature, being intended for a very low speed, had a larger amount of copper on it than usual.

The bearing of these curves on iron-cored alternators and on open circuit-working generally is obvious. With a magnetisation of 12,000, the loss in hysteresis alone, at 100 ∿, would be over 1·5 watts per cubic inch of iron core, and the eddies would amount to a good deal more. I will only add that the eddies, both in the iron and in the copper, are greatest when no external work is being done, as was the case in my experiments. They are reduced by the effects of self-induction when the circuit is closed. A difference exists in this respect between generators and motors, a difference in favour of generators.†

I will not further extend this Paper by dealing at greater length with this part of the subject.

Resumed discussion of Mr. Mordey's Paper on "Alternate-Current Working," Thursday, May 30th, 1889 :—

DISCUSSION (AUTHORISED ABSTRACT).

Before the discussion on Mr. Mordey's Paper on "Alternate-Current Working" was proceeded with, the author exhibited and described an automatic current regulator, arranged to work within half per cent. without "hunting," and also explained a model and drawings of his single-coil alternator. During the week he had received letters, amongst others from Lord Rayleigh, Prof. Ewing, and Mr. Zipernowsky, bearing on his Paper, from which he now read extracts. Lord Rayleigh pointed out that in the *Phil. Mag.* for 1886 he had worked out the virtual resistances of conductors. He also thought the term *frequency* better than *periodicity*. Prof. Ewing referred to the work lost in hysteresis, and Mr. Zipernowsky promised to forward his criticisms later on.

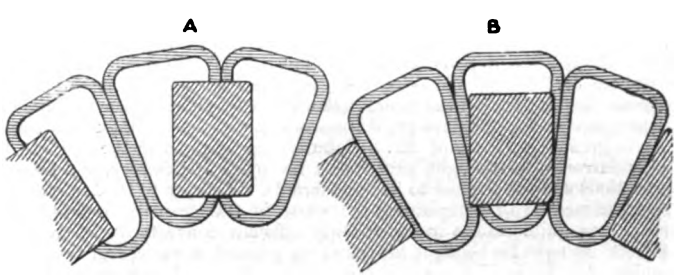
Prof. FORBES read some notes by Dr. Hopkinson, who states that to obtain direct control in parallel working neither large self-induction nor small self-induction are essential, but the best control is exerted when $\frac{2\pi\gamma}{T} = r + R$, where γ = coefficient of self-induction, T = period, and $r + R$ is the resistance of armature and leads. If the resistance of the leads or feeders be considerable, parallel working is more difficult. In his Paper of November 13, 1884, the case of putting generators giving different E.M.F.'s in parallel was shown to be feasible, and from the equations of § 3 the work done by the leading machine becomes zero when $\frac{2\pi\tau}{T} = \frac{\pi}{2}$, where 2τ is the difference in time phase. Dr. Hopkinson also says that all the phenomena observed by Mr. Mordey could be predicted from his 1884 theory.

Prof. THOMPSON read a communication from Prof. Adams, in which attention is directed to the South Foreland trials of 1884, described in his Paper read on November 13 of that year, in which many of the experiments mentioned in Mr. Mordey's Paper were performed satisfactorily. He regarded Mr. Mordey's statement on page 4, that alternators with small self-induction and resistance "will best run parallel because they will be the best synchronising motors," as equivalent to saying that "tuning forks synchronise when in unison." Reference was made to the beats shown by the synchronising lamp when one machine was running at half the speed of the other, and from acoustical analogues Prof. Adams thinks alternators will run as motors at speeds corresponding to fractions or multiples of that of the generator. He attributes the active cause of synchronising to self-induction, and considers that the groaning heard when the machines were switched parallel to confirm this view.

Major CARDEW, referring to the frequency at which the temperature of lamp filaments begin to follow the current, said that in experiments on signal flashes about ten changes per second could be clearly seen. The section on Safety and Safeguards seems to him to imply that the faults *a*, *b*, *c*, *d* must occur simultaneously if a person is to receive a shock, but the speaker thought *a* and *b* may exist unknown to a person who accidentally or otherwise touches the secondary whilst making contact with earth. Earthing the secondary, though safe as regards shocks, might considerably increase fire risks.

Dr. FLEMING, speaking from information recently obtained in Milan, said there was no difference between the average life of lamps worked by direct or alternating currents. As a possible explanation of the observations on the periodicity which gives maximum efficiency, he suggested that for rapid changes the viscous hysteresis was most important, whilst for slow ones the eddy currents penetrated further into the metal, thereby wasting more energy. He thought the Institution greatly indebted to Mr. Mordey for demonstrating successful parallel working without much self-induction or resistance, and pointed out that to work alternators parallel satisfactorily not only must the machines come into step, but they must do so promptly and considerable stability must exist. These conditions may be satisfied by suitably shaping the field poles and armature coils, for on these the shape of the E.M.F. curve depends.

Mr. KAPP complimented the author on his valuable Paper, not as a formality but because it was one of the best ever brought before the Society. In his remarks on the Paper he thought it was not at all clear how the E.M.F. of a machine excited to give 1,000 volts rises to 1,500 when placed in parallel with one giving 2,000 volts, but according to his idea this was probably due to the armature current demagnetising the field of the generator and magnetising those of the motor. He questioned whether the self-induction of the armature was insignificant, for when the field poles were central with the coils they would act as cores for the coils which would therefore have considerable self-induction. This will vary with the relative positions of the magnet and armature, and tend to pull the machines into step.



Mr. SWINBURNE suggested as a satisfactory test of parallel working that the machines should be capable of being kept on full load without undue heating of the armatures. Referring to the word "synchronising," he thought its use in the Paper rather ambiguous, for in some cases it related to speed and in others to phase. As regards the efficiency of transformers working at different frequencies, he thought the comparison ought to be made on different transformers, each designed for the frequency under which it was tested. Under these conditions, and with 50-light transformers, increasing the frequency from 42 to 83 raises the efficiency from 92 to 93 per cent. when worked at full load all day, and from 60 to 62 per cent. when working at full load for two hours out of the 24. From some recent calculations he found the loss from eddy currents in direct-current armatures to be unimportant when thin plates were used.

Prof. S. P. THOMPSON, speaking of arc lamps, announced that he had recently localised the back E.M.F. in direct-current lamps, and found a sudden change in potential of 39 volts at the crater. He questioned Mr. Kapp's statement about the field magnets increasing the self-induction of the armature, for the time was too small (about $\frac{1}{200}$ second) to allow such masses of iron to change their magnetism in obedience to the armature current. Prof. Thompson also gave a graphical construction for showing the distribution of work between two machines of different voltage when switched in parallel.

Prof. AYRTON, having obtained measurements of the self-induction of Mordey armatures by the secohmmeter, was in a position to say that neither Mr. Kapp nor Dr. Thompson were quite correct, for the coefficient was 0·038 in position A (see Figure) and 0·036 in position B ; and both decreased about 14 per cent. when the magnets were fully excited. The frequency of the testing current was about 100 in all the tests. From experiments recently made at the Central Institution on the efficiency of the Mordey transformer, with frequencies varying from 53 to 240, he said there is no evidence of greater efficiency for medium frequency ; on the contrary, the efficiency increases with the frequency, particularly for small loads, and is nearly the same for all frequencies at the maximum working load.

---

* The use of the word "induction" in so many senses is apt to cause confusion. "Magnetisation" would perhaps be better than "induction," "magnetic induction," "density," "magnetic density," &c.

Prof. FORBES thought the fact of the engines driving the alternators when the experiments were made being ungoverned should be clearly stated in the Paper, for this helped considerably to explain the phenomena. He also believed Mr. Mordey was perpetuating an error if he assumed that only two methods of distribution were possible, either separate large machines or small ones in parallel, but it was quite common in America to divide the mains and connect them to separate machines when necessary, and the circuits are so arranged that two or more may be switched on one machine during the hours of minimum demand.

The PRESIDENT (Sir W. Thomson) suggested the expression "cophasedly synchronised" as meaning that the machines were in step both as regards phase and speed. To explain the result of coupling two alternators at 1,000 and 2,000 volts respectively, he considered the current resolved into two components differing by a quarter of a period and having their respective maxima at the positions A and B in the above figure. The latter component would tend to magnetise the motor fields and to demagnetise those of the generator, and in this way produce the observed phenomena. Referring to the single-coil alternator, he thought it a beautifully simple and ingenious machine, and though some loss would arise from magnetic friction, this need not be great.

Mr. RAWORTH, who during the week had made experiments on the E.M.F. curves of alternators and transformers, exhibited a diagram showing the arrangement adopted. The results, though incomplete, were, he said, astonishing, and he thought the question of lag would be settled in a manner not in accordance with theory.

Mr. MORDEY, in reply, said Dr. Hopkinson's difficulty arising from the loss in leads was not a serious one, for the high potential used in transformer systems rendered any considerable loss unnecessary. Referring to Prof. Adams' criticisms, he said he had laid no claim to the invention of parallel working, but had shown it to be perfectly practicable at a time when, in spite of the success obtained by Prof. Adams (to which he had drawn attention in his Paper), considerable doubt existed as to its commercial possibility. He considered Dr. Fleming's explanation of the minimum generation of heat for mean periodicity a very probable one, and mentioned that although the heating at periodicity 125 was more than that at 100, yet the current passing through the transformer was less in the first case. As regards Mr. Kapp's difficulty, Mr. Mordey admitted that a change of 500 volts did occur, and although he had not attempted to explain the matter, yet the straight characteristic given by the machine as a generator was a sufficient proof that as a motor the self-induction could not be great. Speaking of Mr. Swinburn's calculations on the loss due to eddy currents, he thought experiment far more satisfactory, and his observations showed the loss to be considerable. In reply to Prof. Ayrton he said the method of determining the waste in transformers by direct currents was quite safe to use with fairly efficient converters. From Prof. Forbes' remarks he thought his views on parallel working had been misunderstood, for he did not recommend it under all circumstances, but in cases where all the prime motors and alternators would work without requiring a large margin it is a great convenience to arrange the leads and mains so that they may be connected in parallel.

Hookham's Electricity Meter.

The inventor exhibited and described the working of his meter, details of which have appeared in the technical papers [*Electrician*, February 1, 1889, p. 369].

In the discussion which followed, the PRESIDENT asked what precautions were necessary to make the mercury contacts with the commutator satisfactory, and was informed that simple amalgamated line contacts were found suitable, and no appreciable resistance existed even after working many months.

Mr. CROMPTON said it was very difficult to make such meter register accurately for small currents, and in Mr. Hookham's instrument the error was very favourable to the supply company. In this he was corrected by the President and Mr. Hookham, the former of whom also pointed out that any error of this kind should be favourable to the consumer, for a few lamps more or less during the day load would make no appreciable difference to the coal bill of the producer.

Mr. S. JOYCE concurred with Mr. Hookham as to the permanency of good magnets, for he had re-tested permanent magnet instruments after being in use six years, and had found them unaltered. He also inquired whether the meter could be tampered with by the consumer, and the inventor was understood to say that as the cover was sealed on this was impossible.

Mr. HOOKHAM referred to a 100-ampere meter, in which the motor was shunted by German silver, and the temperature effects tend to compensate each other. The process of making the permanent magnets was described, from which it appears that they are first magnetised, and then weakened about 10 per cent., to give them a tendency to strengthen. The great secret of obtaining constancy was said to be making the magnetic circuit as nearly closed as possible, and instruments constructed on the plan described showed no appreciable variation after 18 months' work.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).

A prospectus was issued early this week, announcing that the list of applications for shares in this Corporation would open on Tuesday, the 4th of June, and close on or before Thursday, the 6th. The prospectus announces the amalgamation and purchase of the undertakings and patents of Messrs. Elwell-Parker (Limited), of Wolverhampton; the Electrical Power Storage Company (Limited); the Railway Electrical Contractors (Limited); the Julien Patents for Electric Traction; and the Sprague Patents for Electric Traction and Transmission of Power. The capital of the Corporation is £500,000, in 50,000 shares of £10 each, of which Nos. 1 to 100 inclusive are founders' shares. The present issue is 45,000 shares of £10 each.

The Directors are:—

Sir DANIEL COOPER, Bart., G.C.M.G., Chairman Electrical Power Storage Company (Limited).

JOHN IRVING COURTENAY, Esq., Managing Director Electrical Power Storage Company (Limited).

GEORGE DIBLEY, Esq., Director Andrew Handyside and Co. (Limited).

Sir ROBERT FOWLER, Bart., M.P., Director Metropolitan Electric Supply Company (Limited).

Sir DOUGLAS FOX, J.P., Member of Council of the Institution of Civil Engineers.

HENRY P. HOLT, Esq. (Crossley Bros., Limited, Manchester), Director Elwell-Parker (Limited).

Sir HENRY C. MANCE, C.I.E., Director West African Telegraph Company, late Engineer and Electrician to the Indian Government, Persian Gulf.

JOSEPH MOSELEY, Esq. (Messrs. David Moseley and Sons, Manchester), Chairman Elwell-Parker (Limited).

JAMES PENDER, Esq., J.P., Thornby Hall, Rugby, Director Eastern and South African Telegraph Company.

JOHN B. VERITY, Esq. (Messrs. Verity and Sons, Covent Garden).

H. GRANVILLE WRIGHT, Esq., Ingram House, Fenchurch-street.

The last two gentlemen are Directors of the Metropolitan Electric Supply Company, Limited.

The Managing Director is JOSEPH SMITH, Esq.; the Works Director is THOMAS PARKER, Esq.; the Consulting Engineers are Sir WILLIAM THOMSON, F.R.S., LL.D., D.C.L.; JOSEPH KINCAID, Esq., M.Inst.C.E., and SAMUEL SPRUCE, Esq., M.E., F.G.S.; the Engineer is J. E. H. GORDON, Esq., M.I.E.E., and the Secretary (*pro tem.*) is Mr. A. W. BARR.

The prospectus states that the Corporation is established to supply the enormous and increasing demand for all kinds of electric machinery which has arisen in consequence of the remarkable development of electricity both as an illuminating and a motive power.

In addition to this, the Corporation proposes to supply machinery for electric power for traction and other purposes to which electricity has been applied with so much commercial success in the United States and elsewhere.

The Corporation acquires—(*a*) The works and business of Elwell-Parker (Limited), of Wolverhampton. The progress of this business since its establishment has been one of marked success. More than 500 men and boys are at present employed, and the orders obtained since the beginning of the present year already exceed those received during the whole of the year 1888. The business is taken over as from the 30th September last, from which date all profits accrue to the Corporation.

(*b*) The works and business of the Electrical Power Storage Company (Limited), including the factory at Millwall, and the whole of the English and foreign patent rights and the royalties and profits receivable from licensees in this country and from Continental and American Companies in respect of secondary batteries manufactured abroad under the Electrical Power Storage patents.

(*c*) The patents and business of the Railway Electrical Contractors (Limited), with its present working contracts for railway train lighting.

(*d*) The Julien Patents for the United Kingdom for electric traction, and the Sprague Patents for the United Kingdom for electric traction and transmission of power.

The scheme of amalgamation has been submitted to Mr. W. H. Preece, F.R.S., and Mr. C. E. Spagnoletti, M.Inst.C.E., who report favourably of the amalgamation, and express their opinion that with proper administration and management the returns should be eminently satisfactory.

The Directors of the Corporation consider that a minimum annual dividend of 10 per cent. may be fairly anticipated, and a portion of their annual remuneration and the whole of the profits upon the founders' shares are contingent on such dividend.

In re THE NEW TELEPHONE COMPANY.

Before Mr. Justice Stirling, in the Chancery Division, on Saturday last, a petition for winding up under supervision order was presented by the company itself. Mr. Buckley, Q.C., stated that the company in November, 1884, commenced to carry on a telephone business. The capital of the company was represented by 1,000 shares issued as fully paid-up, and £9,433 paid on other shares. The collapse of the company had been caused by an action having been commenced in March last against them by the United Telephone Company, to restrain this company from working infringements and other patents. An injunction was obtained in that action which had not been further prosecuted. Nothing further had been done by the company, which, unfortunately, had got to the end of its powers. An extraordinary general meeting was held on April 29 last, when the company passed an extraordinary resolution in favour of winding up and for the appointment of Mr. Ogle as liquidator. The debts amounted to £2,339, and assents to the supervision order being made had been signed by the majority of the creditors. His lordship made the order asked.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 25, 1889.

The number of departures for Europe this month has been remarkably large, and I do not know any year in which so many electricians have sailed for Europe, or will do so before the season is over. Of course the Paris Exposition is the great special attraction, and most of the electricians going over have work to do in connection with the exhibits at Paris, or propose to make a special study of what is to be seen there. There are also a great many who will be on the *qui vive* to pick up new ideas and new apparatus for exploitation in this country, and others, again, who propose to see what can be done in placing American systems of light, power, &c., on the European market.

The owners of the celebrated Comstock Lode at Virginia City have for a long time felt that the exigencies of their operations demanded not only more power, but power at such a cost as would enable them to work their enormous quantities of low-grade ore at a profit. They have, at heavy expenditure, carried water from streams in the Sierra Nevada Mountains, 30 miles off, but the supply has never been sufficient, and the working of the mine has been frequently suspended in consequence. A perfect and remarkable solution of their difficulties, however, has just been effected. The stamp mill of the Nevada Mill and Mining Company has a water-power at the level of the mill, supplied from a reservoir at the side of the mountain, and, finding this water-power inadequate for their operations, the company compared notes with the Comstock people. The matter was referred to the Brush Electric Company, through its agents, the California Electric Light Company, of San Francisco, and the speedy result was a proposition to collect the waste water from the surface wheel at the mill, convey it in pipes to the shaft of the Chollar mine, which is close to the stamp mill, and thence down the shaft, until a sufficient head should be obtained to produce the power required. This was a bold scheme, but it was pronounced practicable, and work was begun last winter. At the 1,650-foot level of the Chollar mine a chamber 50ft. long, 25ft. wide, and 12ft. high was excavated out of the solid porphyry, in which the dynamo-electric generators were placed. From the waste surface tank two wrought iron pipes, one 10in. and one 8in. in diameter, are led to the subterranean chamber. At the bottom of the shaft these two pipes are united into a single one 14in. in diameter, from which six 6in. pipes run to the nozzles of the water-wheels provided to drive the large Brush dynamos. Of these there are six, which are mounted on a heavy cast-iron base, and are provided with an extended shaft and outer bearing. On each armature shaft, and between two bearings, a Pelton water-wheel is mounted, enclosed in a water-tight cover. The generators are each of 130 horse-power capacity, and are compound-wound for constant current. Their electrical curve is as near perfection as possible, and they require no regulator. The current is of constant strength under all conditions of load. One of the most remarkable points about this plant, however, is the head of water at the underground chamber, which is 1,650ft. Never before has such an enormous pressure been used for the purpose. The "Pelton" water-wheels, which were selected as the best adapted to the special conditions, are provided with an ingenious wedge-shaped partition, by which the stream of water is divided and sweeps out through the curved sides in such a way as to produce a reactionary effect in addition to the impact, and the water is all thrown down and out of the way of the wheel. The six wheels, which are made of phosphor bronze, are each forty inches in diameter, and weigh 220 pounds, and they drive the generators at a speed of 900 revolutions per minute. The machines are arranged in two parallel rows of three, and work with such perfect smoothness that of the 800 horse-power generated there is no evidence save the motion of the swiftly revolving armatures. Thirty-six Swan incandescent lamps, operated in multiple series from one of the generators, illuminate the chamber, and there are several of the same lamps in the incline. Each generator circuit has a Brush dead-beat ammeter, and a Brush voltmeter capable of measuring up to 3,000 volts is also provided. Any generator can be thrown on to any one of the outgoing circuits by a switchboard in the dynamo room, to which the generator circuits are led. As the circuits of copper wire ascend, one to each generator, they pass through a shower of spray, but the insulation is so excellent that no sign of a leak has yet been seen. The wires are carried above ground to the electric motor room at the Nevada Mill, the length of each circuit being a little more than a mile. The six motors in the motor room are of the regular Brush constant-current type, each of 80 horse-power capacity, and arranged in a single row parallel with the main driving shaft, to which they are belted. The surface wheel, which is also connected to this shaft, uses the water in the first instance and furnishes part of the power to drive the main shaft. The waste water is then carried down the Chollar shaft to the underground chamber, where its drives the dynamo which generates the electric current and energises the electric motors above ground, which in turn furnish additional power to the main shaft. A more complete triumph of adaptation it would be hard to find. Each motor has its own independent circuit fed from one of the generators, and its speed is regulated by the well-known Brush regulator. All or any number of the motors work perfectly in a battery together or with the water-wheel, and they run at a speed of 850 revolutions per minute. An ammeter for each motor indicates at all times the current flowing in each circuit. Some idea of the saving effected by this plant to the mine-owners may be formed from the fact that the surface wheel alone requires 312 miner's inches of water to develop power sufficient to drive 40 of the 60 stamps with which the mill is equipped. As a matter of fact, this amount of water is seldom available. Two of the electric motors, working in addition to the surface wheel, will perform the same work with but 72 miner's inches of water, thus effecting a saving of about 77 per cent. The net commercial efficiency of the plant is about 70 per cent. The waste water from the 1,650ft. level of the Chollar Mine is now, I may add, piped into the Sutro Tunnel, and it is seriously proposed to use this water a third time at a lower level for other work by duplicating the electrical machinery.

The trial trip of the Topeka (Kan) Rapid Transit Electric Railway took place on April 3rd, and the road has since proved a great success. This is the longest line which has yet been built using one system and receiving its current from one central station. The Thomson-Houston Company, which has already done such excellent work in railways, has spared no trouble to make the efficiency of this line of the highest possible order. The road is 14 miles long, and has a total length of track of 20 miles. The power station is a handsome brick building. Its length is 100ft. by 85ft. wide. One-half the building is two stories high, and at the rear is a chimney 125ft. high. The solid masonry of the foundations of the engines and dynamos rests on bed rock, and the utmost stability and firmness are thus ensured. The two engines are of the Corliss type. The smaller engine is capable of developing 300 horse-power, and its fly-wheel, which is 20ft. in diameter, weighs 26,000 pounds. The larger engine is of 600 horse-power, and its 20ft. fly-wheel weighs 20 tons. The smaller engine is situated at the end of the building, and the larger one directly opposite. Both are belted to the main shaft, which runs the entire length of the building. The engines run at 80 revolutions per minute, and there is not the slightest jar perceptible. The foundations are entirely independent, each engine resting on a concrete base, upon which are placed large blocks of stone laid in cement to a thickness of about 10ft. The steam for these engines is supplied from a battery of five boilers, which are of the best quality of steel, and are 6ft. in diameter and 16ft. long. They are located between the engines in a brick enclosure, which isolates them from the dynamo and engine room, and are so arranged that they can be run separately or in series. The feed water is taken from wells 65ft. deep. The water is first pumped into an exhaust receiver and then raised to a temperature of 212° Fahrenheit. The water enters at the top, and is received by a crescent-shaped pan, over the edges of which it runs until it reaches the centre, when it drops into a similarly shaped pan, and so on into another pan, until it passes through 16 different pans. By this arrangement the exhaust steam strikes

Digitized by Google

the water as it drops from pan to pan 16 different times, and removes its impurities. This water is then delivered by a special pump fitted for handling hot water into a superheater which is placed above the boilers. The heater, which is 26ft. long, contains 24 pans like those already mentioned, and it is kept at a temperature of 320 degrees by a full pressure of live steam from the boiler. This high temperature naturally purifies the feed water, and its lime, iron, magnesia, and other impurities collect on the bottom of the pans. The floor of the boiler room is paved with hard brick, and a track for the coal car runs in front of the furnace doors for the transportation of coal. The electrical apparatus consists of five 80 horse-power Thomson-Houston generators for supplying the necessary current. These generators are compound-wound and connected in multiple. A large switch-board is fitted with the necessary current indicators, switches, &c. The cars, already 12 in number, are each equipped with two 10 horse-power motors. The overhead system has been used, and the rails serve for the return circuit.

The annual meeting of the American Institute of Electrical Engineers has been held in this city this week. The proceedings began Tuesday evening and terminated Wednesday evening. At the closing session on Wednesday evening Prof. H. A. Rowland, Ph.D., of Johns Hopkins University, delivered a lecture on "Modern Views in Respect to the Nature of Electric Currents," illustrated by numerous experiments. The lecture was listened to with the greatest interest and appreciation by a representative audience of 350 electricians and their friends, and a more masterly enunciation of the subject in a popular yet scholastic way has never been heard. The American Institute of Electrical Engineers has a great future before it, and that it realises its mission is abundantly evidenced by its sterling contributions to science and its energetic general management. Prof. Elihu Thomson has been elected president for 1889—a man whom we all delight to honour.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *May* 31, 1889.

During the year 1888 the Electrical Department of Messrs. Ganz and Co. carried out 108 electric light installations with 560 arc and 54,000 glow lamps, including 20 central stations and 88 isolated plants. The company has also asked permission from their shareholders to join the Augsburg Gas Company in opening a central electric light station in Innsbruck and other places; further, to join the Union Bank in promoting the International Electrical Company in Vienna, and to take 250,000fl. of shares in this company. This company has since been brought out by the Union Bank with a capital of 3,000,000fl., and it has the right of using all Messrs. Ganz and Co.'s patents for Austria.

The Town Council of Vienna have decided to partially light up the Town Hall with glow lamps, and have given Messrs. Egger and Co. the order.

The electric transmission of power to long distances has been making rapid progress in Austria-Hungary, as may be seen from the following account of work at present in hand or recently completed. Herr Kapferers' paper mill at Waltens is receiving an installation for supplying motive-power to the whole of the works. A 60 horse-power turbine, driven by the Waltens stream near Innsbruch, actuates a dynamo generating current at 500 volts. The current is taken by overhead wires to the mills, a distance of about six miles. Another interesting installation is that in connection with the Wiener-Neustadt Brewery, where both light and power are supplied by means of alternate-current transformers. The water-power available is 80 horse-power. There are 200 glow lamps installed, in addition to two motors of 10 horse-power and one of 5 horse-power. The generator is a Ganz machine, giving 25 amperes and 2,000 volts, and running at 500 revolutions per minute. The two 10 horse-power motors run at 830 and the 5 horse-power 1,250 revolutions per minute. The distance between generating station and the works is 1½ miles. Another plant, not yet erected, but which is in progress, is for the saw mills of Herr Glesinger, in Ober-Turtschek, near Kremnitz, Upper Hungary, where both electric light and power will be furnished by a constant-current machine. There are to be 50 glow lamps and two arc lamps. A fixed electromotor of 2½ horse-power is to be used for drawing the sawn wood by means of a drum a distance of about half a mile to the railway station, which is at a higher level.

NOTES FROM BRUSSELS.

(FROM OUR CORRESPONDENT.)

BRUSSELS, *June* 4, 1889.

The Société Industrielle d'Électricité de Bruxelles is in liquidation. A company calling itself the Société Anonyme Belge pour l'Eclairage Public par l'Électricité has just been formed, with a capital of 250,000fr., in 500fr. shares, to carry out general electric lighting and transmission of power work. The company also proposes to amalgamate with other electrical concerns and to form small local subsidiary companies.

The railway station at Esschen, a small town of 4,000 inhabitants, situated close to the Dutch frontier, has recently been provided with the electric light. An enormous and ever-increasing cattle traffic passes through this station, and a better light than that given by the old-fashion petroleum lamps was urgently needed. The installation was undertaken by the Société Électricité de Hydraulique, of Charleroi, and comprises a Thomas-Laurenz boiler, an engine of MM. Carels Frères, of Ghent, and two 4-pole compound-wound Dulait-Gülcher dynamos. These machines have an output of 150 amperes and 70 volts, and run at 380 revolutions. The lights at present in use are six 12-ampere and four 8-ampere arcs, placed respectively 53ft. and 33ft. above the rails. A large increase in the number of lamps will shortly be made. Every post is provided with a Melsens lightning conductor, and the leads are of bare copper wire, except near the posts. Whenever a lamp is extinguished or gets out of order a bell is rung in the dynamo room, and the needle of an indicator points to the defective lamp.

CORRESPONDENCE.

THE FUNCTION OF THE CONDENSER IN AN INDUCTION COIL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I feel some hesitation in venturing to question any results of a theoretical character which have been obtained by Dr. Fleming, but, as I have some doubt whether his investigation of the function of the condenser in an induction coil exactly meets the conditions, I beg to trouble you with the following view of the matter:—

Dr. Fleming has assumed a primary with capacity at its ends, a secondary with no capacity at its ends, and the possibility of the existence in the secondary of electrical oscillations, *i.e.*, he has assumed that a current can pass in the secondary. If the ends of the secondary are open and have no capacity, then no current can pass at all until sufficient E.M.F. is developed to break through the air, and what happens after this is of little consequence. What is required is to make this E.M.F. as great as possible, and this is accomplished by retarding the primary current as much as possible. Now, without a condenser the primary when broken leaps across the infinitely narrow space at the break, starting a spark which it maintains during its decay—a spark of comparatively small resistance, which requires for its passage by the current a small E.M.F., and therefore $L\frac{di}{dt}$, which is this E.M.F., is also small. Since then the E.M.F. at the terminals of the secondary is also proportional to $\frac{di}{dt}$, so long as no current passes the E.M.F. in the secondary is also small.

Now let the condenser be inserted. Then, as before, the E.M.F. developed in the secondary, which determines whether a current shall be started or not, is proportional to the highest rate of change of the primary. The condenser will only be of service from this point of view in so far as it makes a higher rate of change possible. If it were not for the spark at the break the greater the capacity of the condenser the lower the rate of change; so if it were not for the spark the condenser would do harm, not good. What I have always believed to be the function of the condenser is this:—At the absolute instant of breaking, the current from the primary is diverted into the condenser, so that the E.M.F. between the terminals of the primary does not rise at the rate that it would have done had there been no condenser, and therefore the spark at the break is not started until the contacts have already become

Digitized by Google

separated. It is possible then for the rate of change of the primary to have a higher value before it can produce a spark at the break. If the capacity were sufficient of course no spark would be formed there at all. The production of a spark at the break is determined by the relation between the increase of E.M.F. at the terminals of the condenser, which depends only on the original current, the capacity and the self-induction, and the increase of E.M.F. that would be required to start a spark in the growing space between the contacts. The first of these follows a harmonic law, and the second a law in which, approximately at any rate, the E.M.F. is proportional to the distance *plus* a constant. If the E.M.F. of the electrical oscillations at any time catches up that which would be required to make the spark, the spark will be formed, after which the rate of change of current strength will cease to be very great. The longer this spark can be deferred the greater will be the E.M.F. required to produce it, the greater will be the rate of change of the primary current, the greater the E.M.F. in the secondary, and therefore the greater the distance across which a spark can be started by the secondary.

The volume of a spark, assuming that a spark can be formed, is no doubt closely connected with the quantity of electricity passing through it. This quantity will, of course, when the primary resistance is so small that a great many oscillations would be possible if it were not for the secondary, be greater with a condenser at the break than without, and this I believe to be the gain that Dr. Fleming has found.

As the above is the explanation that I have always given, I should be much obliged if Dr. Fleming or any other learned correspondent would look at the matter from this point of view, and correct me where I am wrong.—Yours, &c.,

C. V. BOYS.

RE "SHEET LIGHTNING" (?).

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am able to confirm Mr. Larden's conclusions by observation as recent as yesterday.

At 9:45 p.m. yesterday evening, looking due north, I observed a flash of sheet lightning which was traversed by five pale sparks passing vertically to the horizon, which was distant from me about a mile, and subtending an angle of about 4deg. I listened carefully for any sound, but was unable to hear any; the paleness of the sparks suggested that they were at a considerable distance.

Several more flashes followed, more or less shielded from view by clouds, but unaccompanied by any sparks or sounds.—Yours, &c.,

JUSTUS ECK.

St. Peter's College, Cambridge, June 3, 1889.

COMPANIES' MEETINGS & REPORTS.

The National Telephone Company (Limited).

The ninth annual ordinary general meeting of the shareholders was held at the City Terminus Hotel, on Tuesday, Colonel R. Raynsford Jackson, the Chairman of the Board, presiding.

Mr. WILLIAM B. CAMPBELL (the Secretary) read the notice convening the meeting. The report and accounts were taken as read.

The CHAIRMAN: I am glad to see that a much larger number of shareholders than usual attend this meeting. I can well understand the reason of their doing so. We have not to deal only with the ordinary business of the Company—that is, to ask your acceptance of the report and the declaration of dividends—but we have also to consider an important scheme of what is practically amalgamation, but which has taken the form of the purchase by the National Telephone Company of the United and Lancashire and Cheshire Companies. I will, however, in the first instance, briefly refer to the report, as it concerns the working of the National Telephone Company proper for the last ten months. I am happy to say that that has been for the Company a prosperous period. We have increased our number of subscribers by 1,489, the total now being 10,813. We have increased the mileage of our trunk wires by 1,238 miles, the total being 3,747 miles. The total mileage of the company's wires is 13,533 miles, and the gross revenue of the Company is now, or rather was on the 30th of April, £125,978. 3s. 1d., the increase for the ten months being £16,405. 10s. 6d., or at the rate of close upon £20,000 per annum. This is the most considerable increase in revenue that the Company has ever managed to secure. We have increased the exchanges of the Company by 18, making the total number 135, and the call offices by 61, making the entire number 277. The net revenue earned for the ten months is £42,338. 1s. 1d., or at the rate of close upon £51,000 per annum. After paying the Preference dividends, the interest on the debentures, and the sum of £3,502. 17s. 9d. due upon old accounts to the United Company with reference to royalties, there is left £24,952. 17s. 9d., which we propose to use as follows:—£9,000 was paid as an interim dividend to the Ordinary shareholders. We propose to make up the dividend for ten months to the rate of 5¼ per cent. per annum, and that will absorb £10,687. 10s. We further propose to put £2,500 to reserve, and to carry forward £2,765. 7s. 9d. I may explain that of the construction outlay, which you see by the report and the accounts for the ten months was £52,747. 0s. 5d., over £16,000 was devoted to the construction of trunk wires, and, as I told you before that we had increased our trunk wires by 1,238 miles, you will understand at what cost the additional trunk wires—a system most important to the interests of the Company and to the public—have been created. You will say if we have been so prosperous—and I assure you that the prospects of the National Company proper are still extremely good—why do we favour amalgamation? We have, as we think, quite sufficient reason to favour amalgamation, and the directors of the Company who remain on the Board are quite satisfied with the terms which have been arranged with the other two companies which are to join in this great and important undertaking. We favour amalgamation for a variety of reasons. In the first place, we think that a necessary consequence will be a great reduction in the aggregate expenditure of the combined companies. You can quite understand that that great reduction of expenditure will be very beneficial to the interests of the shareholders. We think also that we should profit by the experience which has been separately acquired by all the companies joining in the amalgamation, and that we shall be enabled, therefore, to give to the public a better service all round than at present, and that we shall also be able to meet the wants of a variety of interests which, to a certain extent, are now neglected. Bear in mind also that the National Company was in relation, and is at this moment in relation, to the United Company in a peculiar position which may or may not be beneficial to its interests, and which could not be, I think, maintained without detriment to them. The United Company has half the voting power in most of the sub-companies, the National Company amongst them. The sub-companies cannot issue additional capital without the sanction of the United Company, and they are limited in the form of issue they adopt by the will and pleasure of that Company. Now I do not think that any shareholder will be indifferent to the fact that by the amalgamation we get rid of the powers of the United Company with reference to our enterprise, and that we form part of a combined Company which is under no such control. Our hope is that the result of the amalgamation will be to make London the heart and centre of a huge telephonic system, embracing its own suburbs and such of the industrial towns of the United Kingdom as may desire to have constant and easy telephonic communication with it. We hope also, as regards the provinces, that the existing extensive trunk communication which unites many of the towns in the provinces will be greatly improved and extended; and as between the towns in the territories controlled by different companies, we have no doubt whatever that the effect will be to save a great waste of time in negotiation, and to supply trunk services running in the direction that is most consonant to the interest of the public, and best for that of the shareholders. I have no doubt that our enterprise will popularise the telephone—will bring, on the part of the public, a greater feeling of cordiality towards telephonic enterprise and to those who wield it, and that the result will be largely beneficial alike to the shareholders and the public. Most of you have received a circular signed by Colonel Williams. I will offer but a few observations on that circular. This is the one dissentient note in our proceedings. The Secretary has read to you the number of proxies which the Directors have received, and I am happy to be able to inform this meeting that Colonel Williams's circular has not caused the withdrawal of one single proxy, and that the number supporting him—the proxies which he has been enabled to send in—are received from five shareholders, and represent 275 shares. In one paragraph of Colonel Williams's circular he says that the voting to-day will be a farce; that the United Company, in fact, will control the meeting; that the United Company's vote is the sole power—for that is practically the meaning of the paragraph—upon which the Directors rely for carrying out its designs and intentions with reference to amalgamation. Well, the fact is that, laying aside altogether the vote of the United Telephone Company, the Directors have received proxies for 34,494 votes. A three-fourths majority of the shares outside those held by the United Company would be 33,750. The Directors, therefore, have received more than a three-fourths vote, leaving out altogether the United Company's voting power. The Directors have also received proxies which are too late to the number of 945, but, at all events, we may judge of the views of the shareholders who sent those proxies if we cannot count their votes in case of a poll. Then Colonel Williams seems to be in a state of great alarm as to what the Post Office may do, and in what direction it may show resentment at the amalgamation of the three companies. I feel no such apprehension. The Postmaster-General no doubt will be influenced by motives of policy in the course which he pursues. He will not be stimulated by feelings of resentment or indignation because the companies have taken that course which they think best for their own interests. I know well what the action of the department has for years past been in reference to the Telephone Companies—at all events, in reference to the National Telephone Company. Its action has been fair and liberal within the lines laid down and imposed upon us by the License under which we work. I know that the head of that department is a fair-minded and honourable man, because I have had experience of his being so, and the head of the Telegraph Department, who has the principal share in dealing with the Telephone Companies, is also a fair and liberal-minded man, and I apprehend nothing whatever from any illegitimate hostility on the part of the department. I can well understand that if the Postmaster-General either

Digitized by Google

thinks of hereafter buying the Telephone Companies, or some day or other extending his own system in opposition to the Telephone Companies, it will suit his interest better that they should remain distinct, unable to act with vigour, rapidity, and intelligence, and that he should be able to deal with them piecemeal. But although he may have that feeling you cannot suppose that a man holding his position in a powerful Ministry would stoop to any indirect action or interference in his dealings with the Telephone Companies, so I conclude we may dismiss altogether the scare which Col. Williams has attempted to impress upon us in his circular. Well, then, there is an extraordinary paragraph in the circular in which he talks of the large bonus which is to be received by the United Telephone Company and the bonus to be received by the Lancashire and Cheshire Company, and the absence of any bonus to be received by the National Telephone Company. He has called the bonus a bogus capital, but I have yet to learn that the legitimate earnings which are derived from the working of any enterprise and the additional increase consequent in the value of their assets is to be regarded as bogus capital. The value of the shares of the three companies has been fixed by the public, and the basis of our amalgamation is the public view of the value of those shares. The National Company could not under any circumstances, as the purchasing company, give itself a bonus, but the companies have been taken over at the relative value they held in the market at the time the amalgamation was fixed upon. I do not think it is necessary to go further into detail on that subject. I think it is very possible that Col. Williams may make an attempt hereafter to enlighten you, and I hope every attention will be given to what he may have to say on this important subject. But there is one other paragraph in his circular with reference to which I would like to say a word or two. He speaks of Messrs. Carter and Carter, and he calls them independent and disinterested experts. I have no doubt he is perfectly right in that expression. He speaks of myself and those who he supposes have negotiated the terms of this amalgamation as neither independent nor disinterested. I am sorry that Colonel Williams has seen reason to change a strong opinion he held in reference to myself, which he expressed in a letter to me upon the 6th April. I will read you the letter. It is short. It is pithy. It is wonderfully well expressed, and I believe it contains—I am convinced it contains—the honest sentiments which influenced Col. Williams at that time, He said then, "I have your letter *re* amalgamation, and will be with you at your informal conference the day before the meeting on Saturday the 11th. It would of course be absurd on my part to offer anything worth calling an opinion upon details which need so much earnest study to master and then to weigh as those which had been occupying your time and attention almost exclusively for months past. As I know and feel that your judgment in such matters is exceptionally strong and sound, and that you have nothing more at heart than the interest of the Company, the success of which is mostly due to your perseverance and skill, whatever you recommend I shall heartily support." He goes on to say: "Of course I see that the scheme involves my own eclipse, and I frankly own that I shall regret to have to disappear, but I have never let personal considerations weigh with me for a moment in a question of this kind, and I accept beforehand your recommendation whatever it may be." Col. Williams will probably when he addresses you explain his reason for the great change in his opinion since then. I must confess that I regret he has seen reason to change his opinion. I doubt whether he will be able to convince you that he was justified in making that change. Before I sit down I will tell you briefly what the capital of the reconstructed company will be. You are aware that the first intention was that the shares of the United Telephone Company should be taken at £15, the Ordinary shares of the National at £6, and the shares of the Lancashire and Cheshire at 31s. 6d. When the Postmaster-General refused to grant the License to the new company to which the property of these three companies was to be transferred we had to consider whether we could still arrange the combination which we thought so essential to telephone interests, and it was decided at last that the National Telephone Company could not increase the value of its own shares from five to six pounds, and it was arranged, therefore, that one-sixth should be taken off the price originally intended to be given to the other two companies, and the result of that arrangement is this: that the United will receive £1,250,000, the National £720,000, the Lancashire and Cheshire £525,000. When I say that the National will receive, I should say that the National has and that the other two companies will receive the amounts I have mentioned; but the United Company hold shares in the National and Lancashire and Cheshire Companies, and the amount allotted to it includes the value of those shares. They are also included in the statement I have given you in the amount of the shares designated as belonging to the Lancashire and Cheshire and National Companies. They will have to be deducted from the total sum which I have put before you. The shares the United holds in the National Company are 45,000 £5 shares, at a value of £225,000, and in the Lancashire and Cheshire Company 50,000 shares at a value of £65,625. These two together make £290,625, so that the amount of the capital of the three companies in the first instance will be £2,204,375. I do not know, gentlemen, that there is any occasion for me to occupy your time longer, and I will now content myself with moving the adoption of the report.

Mr. JOHN BRUCE seconded the motion, which was carried unanimously without discussion.

The dividends recommended at the rate of 6 per cent. on the Preference shares and of 5¼ per cent. per annum on the Ordinary shares, both for the ten months to April 30, were declared.

Mr. JEREMIAH GARNETT moved the re-election of Colonel Jackson as a director.

Mr. PETER GARNETT seconded the motion, and it was carried.

The CHAIRMAN, in returning thanks, explained that the term of office of the Directors would be a very short one if the amalgamation were carried through, because the amended Articles of Association provided for a new Board. The Chairman then moved the re-election of Mr. W. H. Bradbury as a Director.

Mr. P. GARNETT seconded, and the motion was adopted.

On the motion of the CHAIRMAN, seconded by Mr. S. H. SANDS, Mr. William Lowson was also re-elected a Director.

The auditors, Messrs. Welton, Jones and Co., were likewise re-appointed.

The CHAIRMAN: The next resolution which I have to propose is the following:—

"*That the following agreements be and the same are hereby adopted and confirmed, namely, an agreement made between the United Telephone Company (Limited) of the one part and this Company of the other part, for the transfer of the United Company's business and certain property to this Company for shares in this Company, and also an agreement made between the Lancashire and Cheshire Telephonic Exchange Company (Limited) of the one part and this Company of the other part for the transfer to this Company of the business and certain property of the Lancashire and Cheshire Company for shares in this Company*"

Now, gentlemen, having said what I thought it expedient to say on the question of amalgamation, I will simply propose that resolution.

Mr. PETER GARNETT seconded the proposition.

Col. WILLIAMS said that in discussing this question the first thing they had to settle was what was meant by the National Telephone Company. The term was a very simple one, but it covered more than one meaning. It meant, on the one hand, a group of *bonâ fide* investors who were not engaged in any financial or other operations with any other company, and, on the other, it meant a group of financiers who had practically the command of the telephone system of the United Kingdom, and the interests of these two bodies were not only distinct but they were antagonistic. The antagonism remained dormant so long as the question of amalgamation was not brought to the front, but it became acute as the negotiations progressed. The interests of the two groups were so diametrically opposed that it was impossible for a Director to serve both parties fairly. That being the case it was perfectly natural that Colonel Jackson should be rather shocked that a Director of this Company should run counter to the interests represented by the group he was serving; but it was just as natural for him (the speaker) to be astonished that the Chairman of the National Telephone Company should disregard the interests of those who had invested money in it as *bonâ fide* shareholders. Colonel Williams went on to refer at length to the course of the negotiations, and said he had at the meetings at which the matter had been brought forward, objected strongly to the amalgamation, on the double ground that it would run counter to the Post Office Authorities without producing any compensating advantages for the shareholders. Colonel Harrison, whom he regretted not to see present, opposed the scheme on its merits, while he (the speaker) having no data upon which to discuss the scheme from that point of view, had opposed it because of its impolicy. But besides that another Director had told him in conversation that he would oppose the scheme if he were independent, but that if he had to be executed he would prefer to chose his own method than submit to the caprice of an executioner. It was clear to him that the Board were under the thumb of the United Company. The terms were, in fact, settled by Colonel Jackson, although he only had authority to get matters sufficiently forward for the Board to discuss them. He could quite understand that if there were any great advantages to be obtained by the amalgamation the opposition of the Post Office might be set aside, but he saw no such advantages, at all events for this Company. Indeed, he considered it monstrous that the United Company should be given two and a-half shares in the amalgamated undertaking for every share held by the National Company. He had invested his money in the Company believing it to be thoroughly sound, and he would be prepared to double or treble his interest if the scheme were withdrawn; but if it went on he would sell his shares at any sacrifice, and he would advise others to do the same, for the bargain proposed was a most inequitable one.

Mr. W. A. SMITH (Glasgow) said that as Colonel Williams had made rather a point of representing the outside shareholders of the National Telephone Company, he (Mr. Smith) thought he might claim attention for a moment, as he represented between a fourth and a fifth of the investing class of shareholders, which was a much larger body than Colonel Williams represented, and in carrying out their views he wished to speak strongly in favour of the amalgamation taking place. He had listened with great patience to Colonel Williams because he was sure what he had said had been said with sincerity; but he was equally sure that Colonel Williams had not devoted sufficient time and attention to be able to fairly discuss such an operation as this. He (the speaker) had gone most carefully into all the figures. Colonel Williams represented that the patents of the United Company would run out in about two years, but it was to be remembered that the value of any successful patent was greater in the last two years of its existence than in the first seven. The United Company owned territory that could be made exceedingly valuable. It was well known that the United Company's Board was composed of men of undoubted talent, but the time of most of those gentlemen was taken up with other matters. Under the scheme of amalgamation, however, they would have a thoroughly representative Board, and if they had proper management he had no doubt they would all have reason to rejoice that the amalgamation had taken place. By the courtesy of the Post Office authorities he had inspected their two exchanges, one in Newcastle and the other in Leicester. The Newcastle exchange appeared to be the supreme effort of the Government department, but it was a poor thing, from which they would have nothing to fear, while the Leicester exchange was a perfect *fiasco*. He trusted that the meeting would unanimously—at all events, with the exception of Colonel Williams—support the Board in this amalgamation, and he suggested that in sending out notices for the confirmatory meeting they should give some fuller particulars of the advantages to be gained by

Digitized by Google

the scheme, feeling that if that were done the shareholders would cordially support the Directors.

Mr. J. GARNETT: As I am the Director whom Col. Williams met at the Reform Club I would like to say a few words with reference to that conversation; but before doing so I would like you to understand that it is usual when a man is taken up for any crime for the policeman to caution him when he speaks that whatever he may say will be taken down in writing and used in evidence against him. But I am not the only gentleman that Col. Williams has done the same thing to. What I did say was this: "I believe the National Telephone Company is by far the best of the three," and I think so still. I believe that we have districts which are far more capable of being improved than either the United or the Lancashire and Cheshire, and I said "I did not think we should ever get the price that I should put upon it. Some of us, you in particular and myself, may have to retire from the Board. We are going to be executed, so we may as well assist at our execution and get it over as easily as possible. I shall go to the Conference and try and get for the National the best possible terms we can get, and I recommend you to do the same." Col. Williams may well know nothing about the negotiations, for he kept out of them consistently. He had an invitation to go to these hole-and-corner meetings that he suggests were held; he was invited to see everything that passed, but he declined to go. I think when the United Company say they have been sold, and the Lancashire and Cheshire declare they have not got what they ought to get, we ought to be pretty well satisfied with the arrangement.

Colonel WILLIAMS said the greater part of the conversation described by Mr. Garnett was purely apocryphal. The account he (the speaker) had given of the conversation was absolutely correct.

Mr. GARNETT denied this, and reiterated that he had stated with practical accuracy everything that he had said upon the occasion referred to by Colonel Williams.

The CHAIRMAN: I shall not detain you by making any lengthened reply to Colonel Williams' observations. I will merely point out that in a few of his facts, which certainly would be important if correct, he is altogether mistaken. He talks about two financial groups, and says he has discovered or has been told that the shares of the Company are held mainly in a few hands. I have before me here a list of the ordinary shareholders of the Company. I have not before me now a list of the preference shareholders, but there are 480 ordinary shareholders in the Company, and the shares are distributed very widely. Many holders have a very few each, and no single holder outside the United Telephone Company has above 1,500 ordinary shares except a bank, and that bank holds the shares of other people, and has sent its proxy in accordance with their desires and instructions. Then, Col. Williams says he has had no opportunity of understanding what was going on with reference to amalgamation. At every meeting of the Board I have entered into explanations upon that subject, and a resolution was passed desiring me to continue the negotiation, and when it had arrived at such a point that I should be able to state what financially and as regards its organisation was proposed, I should then explain the features of the negotiation to the Board. We had lengthened negotiations before we arrived at that point, and as soon as we had arrived at it I took the Board into my fullest confidence. Then he says in his circular that I alone represented the National Telephone Company. I have been assisted at various times by other members of the Board in my conferences with the directors of the other companies—both the Messrs. Garnett, Mr. Sands, and Mr. Bruce have all attended these conferences with me from time to time, and when the most important conference of all took place those four gentlemen were, as well as myself, present. Then Colonel Williams says that only two gentlemen from the United Company took part in those conferences, and two from the Lancashire and Cheshire did so. It so happens that the whole of the Board of the Lancashire and Cheshire Company was present, and generally three or four of the United Telephone Company, so that Colonel Williams has not been quite so careful in ascertaining the correctness of his facts as when intending to address a meeting of this importance he should have been. I shall not further enter into the matter.

The resolution was then put and carried, Colonel Williams being the only dissentient.

The CHAIRMAN: The next resolution I have to propose is:

"*That the capital of the Company be increased by the sum of* £3,250,000 *by the issue of* 650,000 *shares of* £5 *each.*"

Mr. JOHN BRUCE seconded the resolution, which was carried.

The CHAIRMAN also proposed:

"*That the regulations of the Company be varied by substituting for the existing Articles of Association the Articles a print of which is now submitted to this meeting, signed for verification by the Chairman of the meeting and the Secretary, and that such last-mentioned Articles be the regulations of the Company in the place of the existing regulations.*"

Mr. J. GARNETT seconded, and the proposition was adopted.

The CHAIRMAN: I may inform you who are to be the new Directors of the amalgamated company. They will be Mr. Charles S. Agnew, who is a representative of the Lancashire and Cheshire Company; Mr. John Winterbottom Batten, one of the United Company's Directors; Mr. James Brand, the present Chairman of the United Company; my friend Mr. John Bruce, Mr. James Staats Forbes, the Vice-Chairman of the United Company; Mr. Peter Garnett, a Director of the National Company; Mr. Eli Heyworth, one of the Lancashire and Cheshire Directors; myself; Mr. F. R. Leyland, a Director of the United Company, who is largely interested in our own Company; Mr. J. B. Morgan, Mr. Dillwyn Parish, and Mr. W. C. Quilter, M.P., all of the United Board; Mr. G. H. Robertson, Mr. Samuel Herrick Sands, and Mr. Alderman Joseph Thompson. Seven of the directors will represent the United Company, four the National, and four the Lancashire and Cheshire. The Chairman then moved a resolution removing all the existing directors of this Company as from the date of the confirmatory meeting.

Mr. FREDERICK R. LEYLAND, in seconding the motion, said that although he represented the United Company on the National Board he had a larger interest in the latter company than in the former. He quite agreed with everything that fell from the Chairman as to the desirability of this amalgamation, and he could from personal knowledge vouch for the absolute truth of what had been said in support of the scheme. Unlike Colonel Williams, he had been present throughout the negotiations. All the new Directors would have an enormous stake in the new National Company; they would represent an interest of £350,000. What better guarantee than this could the shareholders have that these gentlemen would attend to their own interests?—and their own interests were precisely the same as the interests of the general body of shareholders. Colonel Williams said the new Company would be dominated by a group of financiers. He did not quite know what this meant, or to whom Colonel Williams referred.

Colonel WILLIAMS: I spoke on the authority of Colonel Harrison.

Mr. LEYLAND thought it would be better if Colonel Williams spoke from information within his own knowledge; but instead of doing so he always expressed the strongest possible opinions, and adhered to them, without having any knowledge or information upon which to base his statements. The negotiations were perfectly open to Colonel Williams, and yet that gentleman had roundly charged the Chairman, behind his back, with having sold the National Company. Indeed, he now insinuated the same thing, though in much more guarded terms. But what interest could Colonel Jackson possibly serve in selling the Company? He had no interest in the United Company, and his whole reputation was involved in this Company. It was cruel for Colonel Williams to make these unjust accusations without any foundation beyond his own diseased imagination. The Chairman had said nothing in his own defence; he was quite willing to leave his character in the hands of the shareholders and of the Directors, who knew and appreciated his great services to the Company. Colonel Williams seemed to forget that the United Company not only had its exchange business, but that they had their royalties for two years longer. Was that worth nothing? Last year the royalties amounted to £45,000. Besides that the United Company would bring in their shares in the subsidiary companies, which were valued at over £400,000. That was what Colonel Williams called bogus capital and premiums. Why, they were *bonâ fide* assets worth golden sovereigns in the market. The negotiating Directors looked sharply after the interests of their own companies, and each man tried to do the best he could for his own company. In this matter the Chairman of the National Company was certainly not behindhand. As to the statement that they were defying the Post Office, that was absolutely fallacious. They were merely trying to give an efficient service at the cheapest rate possible, so that the Company should be defended from competition by the Post Office or by anybody else, or should, at all events, be able to face without fear any competition which might be forced upon them. Colonel Williams had also stated that the National Company had been terrorised and menaced by the United Company; but that was a pure myth. He said this with some authority, for he had been present at every meeting, whereas Colonel Williams, who made the charge, was not present at any of them.

Mr. J. S. FORBES: If anybody knows anything about this matter it is myself, for I have been entrusted by the United Company with the leading oar in the negotiation. I shall not refer to Colonel Williams, for I think his position is sufficiently unfortunate. He has ventured to make statements without knowledge and upon hearsay, and I think he cuts rather a sorry figure now he is exposed. Perhaps he will go away from this meeting having learned a lesson; let us hope so. But in case there should remain the possibility of his circular affecting the mind of any shareholder in the National Company as to its being a bad bargain for him, perhaps it will be a consolation for you to know that I, for one, think they have got the best of it. I most reluctantly consented to the terms being accepted for the United Company, for I was quite satisfied that the United Company got the worst of it. But, oddly enough, when we came to talk to the Lancashire lads—they are largely interested personally in the matter, and are generally credited with knowing how many shillings there are in a sovereign—we found that the cleverest man amongst them and the most obstinate was still dissatisfied; so that it comes to this: The National have made a very bad bargain in this amalgamation, the United have made a very bad bargain, and the Lancashire and Cheshire have made a very bad bargain. Now, my induction from that, as a man of the world, is that you can depend upon it when every party to a bargain is dissatisfied it is about the right thing all round. I commend that to your consideration. I do not think it necessary to deal further with that matter; but I must say a word or two as to the personal aspersions on Colonel Jackson. Colonel Jackson knows that about myself there has been no sentiment in the business, and I have appreciated as much as any man can do, not being a shareholder in the National Company myself, the great services he has rendered to your Company, because I am satisfied that, first of all in building it up and giving it a market value and, defending by argument and tenacity that market value, he has done you in the carrying out of your undertaking enormous service. It is greatly to his personal merit and attention that you owe the fact of the present market value of your property, and, lastly, he has secured for you an exceedingly good bargain. Then, about the Postmaster-General; let us get rid of all that. I know the Department pretty well, and I have the honour of the personal acquaintance of the Postmaster-General. He is only doing his duty in protecting his interests, but I agree with the Chairman in thinking that the Postmaster-General could not descend to being influenced by any feeling of anger because you are protecting your interests and availing yourselves of your legal right. You cannot go outside it, so you may get rid of any idea that the Postmaster-General is going to be greatly offended. If he should be weak enough to be offended you may get rid of any fear that that would influence your future. You have an enormous business, and the reason that the amalgamation is likely to be

Digitized by Google

useful is that when the patents expire you will be able to protect yourselves against the competition of the Post Office or anybody else. The patent is sufficiently protected to enable you by a judicious expenditure of capital to put your house in order, and with the knowledge we have of this enterprise—knowledge which nobody else has of this business—to place yourselves in such a position of security that when the time comes for open competition you can defy not only the Postmaster-General and the Department but any outsider also.

The resolution was then put and agreed to *nem. con.*

The CHAIRMAN then proposed the fourth resolution:

"That in order to give effect to the regulations of the Company all the Directors holding office prior to their adoption be removed from office."

This resolution was seconded by Mr. SAMUEL H. SANDS and carried.

On the motion of Mr. FITZGERALD a cordial vote of thanks was passed to the Chairman and the Board of Directors.

The CHAIRMAN acknowledged the compliment, and the meeting then closed.

United Telephone Company.

The ninth annual general meeting of this Company was held at the City Terminus Hotel on the 4th inst., under the presidency of Mr. James Brand.

The SECRETARY (Mr. Thomas Blaikie) read the notice convening the meeting.

The CHAIRMAN said: Gentlemen,—During the last few months your accounts have been subjected to very severe inspection by our two subsidiary companies with whom I hope you are now going to amalgamate, as well as by our own auditors. They have all agreed that we can pay you a dividend of 17½ per cent. while we increase your reserve fund by about £10,000, arising from premium on new shares issued. Your share capital is now £500,000, against £483,000 last year. This is an increase of £16,500, partly owing to the amount called up on the new issue of shares after the end of our last financial year, and a further issue since of the remaining 978 shares. On the whole of this amount the 17½ per cent. dividend has to be paid, making an increased payment to the shareholders of over £9,000. As to revenue, we carry forward £4,000 more of unearned subscriptions for the benefit of next year. I will not say any more as to the accounts just now, but by-and-bye will be happy to answer any question that may occur. I will say a word or two as to what we have been doing, and then get on to the resolutions for amalgamation. To meet the wishes of many subscribers we have established an all-night service throughout the West End of London, Chancery-lane, King's Cross, &c. At present this means chiefly an increase of expense, but we hope it will more and more prove the usefulness of the telephone and add to the number of our subscribers. So far the calls have been very few, but they are gradually rising, and last week they averaged 123 per night between the hours of 9 o'clock p.m. and 9 in the morning, and on Sundays 216. We have now 28 call rooms in and about London open. We have nine more to be opened shortly, and we have concluded an arrangement with the Aërated Bread Company which will very soon cause the opening of something like 80 fresh call rooms in the most frequented places in London. A local exchange has been opened at Bromley, in Kent, which is now being joined to our London system by trunk. We have already an independent trunk line between London and Croydon, and a local exchange with 42 subscribers. The number is few, but we have worked very hard to get them. To encourage the enterprise we have put the Croydon people on the system, and joined up the medical men free of charge. The Brighton business in itself is, I believe, doing very well for the South of England Company, but we have not had the success we hoped for as far as the inter-communication with London is concerned. We believe this to be owing to the uncertainty of our wire. This was put up on the ordinary railway telegraph poles by the General Post Office. It has cost us a good deal of money, which except as a useful experiment has been more or less thrown away. The South of England Company has now entered into a special arrangement with us for the purposes of a call room between London and Brighton. The route has been surveyed and the work begun, so that we may join our Croydon trunk wires on the Brighton direct or special poles, which will be free from induction, and we hope to induce a large telephonic business between London and Brighton and the intermediate towns. I am glad to tell you that we have acquired space within the Stock Exchange of London, and are erecting a special trunk line between the Stock Exchanges of London, Liverpool and Manchester, entirely for the use of the members of these Exchanges. Our trunk is now complete for nearly 94 miles between Birmingham and London, and, barring the difficulty of getting way-leaves about Hampstead, the London end will be complete in a week or two. The road to the north of Birmingham is being surveyed. Through the National Company's wires now in existence beyond Birmingham we hope to put the Stock Exchanges in communication very shortly, and to put them in perfect communication by the special trunk in a few months. If this line is a success, as I fully believe it will be, it will have a very valuable effect on your property, or rather, as I hope, on the property of the Amalgamated Company. At the date of the general meeting last year we had obtained an interim injunction against the Equitable Telephone Association, restraining the use of the Campbell-Swinton Telephone, and the defendants in that case threatened to fight the whole question of the validity of the patents, as also the question of infringement. But I am glad to say that they thought better of this, and in December last they submitted to a perpetual injunction with the usual terms, surrendering all instruments in their possession, and giving particulars of all instruments supplied. The Company speedily went into liquidation. We have since had to take action against the New Telephone Company, to restrain the manufacture and sale of Silvanus Thompson's Valve Telephone. In this case again we were threatened with a heavy fight, but after we had given notice of motion for an interim injunction they surrendered at discretion, and the result has been the same as in the case of the Equitable Telephone Company. The Court made a winding-up order against them on Saturday last, and I am afraid that the people who have been buying instruments from them on the faith of their indemnity will find their indemnity of very small value. We have, as you are aware, throughout adopted the policy of waiving proceedings against purchasers and users of these instruments on their giving up the offending instruments. Some 2,000 instruments have been surrendered during the past twelve months, and the various district companies have in very many cases supplied licensed instruments in their place. It is not a very wise thing to prophesy, but I really think that in the face of the complete collapse of these infringing companies, leaving their guarantees unpaid and their shareholders with a total loss of their capital, we are not likely to see any similar company started during the remainder of the terms of the patents. You will wish now to come to the question of amalgamation, which is the most interesting question to-day, and I shall have this afternoon to propose some resolutions, which I hope you will pass, to enable us to carry this amalgamation into effect. We first considered this matter about two years ago, and as time went on it became more and more evident to us that amalgamation is the right course for us to pursue if we want to turn our investment in telephonic enterprise into a really high-class security or property. When first we entered into this enterprise we found that our one combination was not sufficient to carry on and develop an entirely new business all over the country at once, but that to enable us to cover the ground without delay it was necessary to divide and scatter our forces all over the country as much as possible, and to enlist the interest and sympathy of all classes of people and in every centre of population and industry. This was done by the establishment of the Lancashire and Cheshire Company, the National Company, the Western Counties Company, the South of England Company, the Northern, and the Telephone Company of Ireland. These companies have excellently proved the wisdom that dictated their formation, and the various towns all over the country are now more or less feeling the benefits of telephony. But the division of the country and the districts in which the United Company and its subsidiary companies are allowed to carry on their business has given rise in many instances to differences of opinion and complications, which has rendered it necessary to come to special agreements when we have wished to put towns and districts and systems in direct communication with one another. By the union all these difficulties and differences will be overcome, the work will be carried out under one management, and when way-leaves have been obtained in the various localities the building of the trunks will be more rapidly carried out. Economy in management will result, decisions as to policy will be more rapidly arrived at, and more power to our elbows will ensue. Following out the same train of thought, while it was necessary in the first place to distribute our energies by the division of our forces, it becomes, now that our purpose has been to a great extent achieved, desirable in the face of the quick approach of the expiration of our patents to once more bring our components together so that we may make up by the concentration of our forces and our business any loss of power which might ensue from the expiration of our patents. Besides, our friend the Postmaster-General, who in the pursuit of the duties of his office acts as a very keen trader always on the look out seeking whom he may devour, would certainly be more able to bring his devices to pass if he had to deal with the various companies singly and one after another than if he had to deal with one great company, strong in unity, in financial position, and with one strong executive body. I really don't know what more I can say or that it is necessary for me to say to put before you the great advantages of this union in the first place of the United Company and its two elder children. The union will have the same effect as the tying together of the bundle of sticks in the fable. While we are apart anyone can try to break us and interfere with us in many ways, but when we are tied up together we become an altogether article, and much more capable of defence and of resisting offensive treatment by any person whatever. While we are separate we are to a certain extent financially as well as otherwise weak, but when we amalgamate we have much greater ease with finance, and can raise money on much cheaper terms, and our shares, which up to this time have been of a somewhat speculative character, owing to the various difficulties which beset us, become property, according to my mind, of a more valuable kind and quality. We have told you in our notice the reason for uniting the three companies also, under the name of the National Company, instead of, as would have been more natural, the two other companies coming together under the wing of our Company, the United Telephone Company. It is naturally somewhat hard for us to change our name, but we have to look at the welfare of the whole body, and not be guided by our individual feelings. We must, therefore, eat the leek provided for us by the Postmaster-General in declining to grant the United Telephone Company permission to assign its License, which would have obviated this necessity without in any way interfering with the rights and interests of his department or the Government. I understand that the Postmaster-General declined to grant us what we desired on the ground that the monopoly created by such a License and by such acquiescence in our desires on his part as might be implied by such a grant would be contrary to public policy and injurious to the interests of the public by the clearing away of competition. Now, when he said this the Postmaster-General was drawing a red herring across the scent of the public. He knew full well that ever since the granting of the separate Licenses to each company there had been no competition, as each company has worked its own territory without interfering with its neighbour, and have all been working to one end and for the joint benefit of the public, themselves, and the United Telephone Company. Why the Postmaster-General refused to grant the

Digitized by Google

permission we asked for is not very clear; but if he had been perfectly frank with us he might have put it somewhat as follows: "You, gentlemen, bought with a large expenditure of your money an entirely novel and most amazing invention. We, the Department, had had just as good a chance of buying this extraordinary thing for ourselves, and so adding immensely to the power of the Department for the public good. However, as we were so shortsighted that we failed to recognise the beauty and value of the thing, we allowed you and your friends to step in and take the invention for yourselves, believing that it was a plaything and you would soon lose your money and get tired of it." As soon as we had proved that it was no plaything, but was going to be a commercial success to the country and a source of profit, he stepped in and said, "Your great invention is only a telegraph, after all. It belongs to us, the General Post Office, and if we allow you to use it you must pay us £10 out of every £100 gross you receive." And a gross thing it was. [Mr. FORBES: "Oh!" (Laughter)] Well, we paid him this enormous tax, amounting now to near, say, £35,000 per annum, which costs him nothing to collect, and now, finding that in spite of this burden placed upon us we are getting stronger and more useful every day, he pursues the old tactics of placing every obstacle in the way of our progress, and reminds me of the wicked husbandmen in the parable, who said: "Here is the heir; come, let us kill him, and his inheritance shall be ours." Gentlemen, the fate of those husbandmen was not a happy one. What he really fears is what we hope, which is that the union of the Telephone Companies will lead to better management, greater economy, and better service to the public, and the possibility in the end of a cheaper exchange system. I think I need say no more to induce you to pass the resolution I have to propose. Remember that union is strength, and in the matter of telephony it means also economy, efficiency, and cheapness. I beg to move the following resolution:—

"That the report and accounts, taken as read, be received and adopted, and that a dividend for the half-year ended 30th April, 1889, of 12s. 6d. per fully paid-up share, less income tax, be paid, making a total dividend for the year of 17½ per cent. on the paid-up capital of the Company."

The DEPUTY-CHAIRMAN (Mr. J. S. Forbes): I beg to second that.

A SHAREHOLDER: Will you take the discussion, if any, on the report separately from the discussion on the amalgamation.

The CHAIRMAN: Yes. The motion is now before the meeting for the adoption of the report and the declaration of the dividend. As many as are of that opinion please signify the same in the usual manner.—To the contrary. Carried unanimously.—Continuing, he said—I have now to move

"That the agreement submitted to this meeting, and expressed to be made between this Company and the National Telephone Company (Limited), for the amalgamation of the two Companies, by a transfer of the business and property of this Company (with certain exceptions) to the National Telephone Company (Limited), in consideration of shares in that Company, be and the same is hereby approved."

That is the agreement for confirming the arrangement that has been submitted to you all in this circular. I do not know that I have anything to say about it more than you have read.

The DEPUTY-CHAIRMAN: I beg to second that resolution.

A SHAREHOLDER: Will there be no alterations in the Articles of Association?

The CHAIRMAN: Oh, yes. They have been exhibited, and are here now—not of our Company, but of the National Company.

A SHAREHOLDER: What are the "certain exceptions" referred to in the resolution?

The SOLICITOR (Mr. Crisp): We do not transfer the License; we do not sell the shares of the National Company which we have, as there would be no object in selling them; and thirdly, we reserve the dividend just declared.

A SHAREHOLDER: What will be done with the shares?

The SOLICITOR: They will be distributed among the shareholders.

A SHAREHOLDER: May I ask if the Postmaster-General can with any effect raise the objection to this amalgamation that it is contrary to public policy, and that we are endeavouring by a side-wind to carry out what he has done his utmost to prevent? There is a question to be asked in the House of Commons to-night.

The CHAIRMAN: We saw that question on the paper too late for us to endeavour to have the effect of such an insidious question neutralised.

A SHAREHOLDER: I do not suppose the Postmaster-General will acknowledge himself to be defeated.

The CHAIRMAN: We know that we are well within the law, and the Post Office Authorities know that too. We are not endeavouring by any side-wind to attain our object. As the Postmaster-General would not let us unite in the way that was most proper we did what was open to us to do by arranging to unite under the banner of the National Company. What we have done we have done most openly, and I regret to hear the expression side-wind used.

A SHAREHOLDER: I did not say that we had acted by a side-wind, but that the Postmaster-General might say that we were trying to carry out our wishes by a side-wind.

The CHAIRMAN: No doubt.

A SHAREHOLDER: Will he not take some action by litigation?

The CHAIRMAN: Well, we must take the gifts the gods provide.

A SHAREHOLDER: It is well to look things in the face.

The CHAIRMAN: We have done so, and the result of looking things in the face is this proposed amalgamation.

Mr. F. R. LEYLAND: I think I may say this in reply to that, as it is a very material point. The Postmaster-General has an undoubted right to refuse to allow us to transfer our license. That we cannot contest, as it is incontestable; but as each company has a license over the whole United Kingdom he has no power to prevent us from selling our Company to another of the companies that has that license. It is not an evasion at all. It is the exercise of a right that we have, and we have taken very great care by consulting with the best counsel at the bar to see whether we are right in our view, and we are told that there cannot be a shadow of doubt about it—that we are strictly in our right. In fact it has never been insinuated by the Postmaster-General that we are not doing what we have a perfect right to do. He would have stopped us quickly enough if he could.

A SHAREHOLDER: I do not wish to detain the meeting, but I desire merely to say that after looking as carefully as I can at what is proposed I can see no objection which is reasonable that can be taken to the directors' action. As regards the Postmaster-General, I do not think we should be afraid of him. He is not likely to do anything of an oppressive character to us in the future. He is the head of a great department. We are not taking advantage of him in any matter, and are not acting by a side-wind at all. I only now wish to point out one thing which I consider of very great importance—that is, the information which the Chairman has given us as to infringing companies. I forget how many instruments he said had been given up. (The Chairman: 2,000.) He also stated that practically all opposition to the validity of our patents had been finally "squashed." That is the most important piece of information, I think, that he could have given us as to our future.

A SHAREHOLDER: I see that the Directors of the new Company have the power to appoint a Managing Director. A great deal has been said about the Managing Director of this Company, and that he is so much occupied that he cannot attend to our business. I should like to have had a promise from the Board as to what they are going to do in the exercise of that power. I speak to a great extent as a telephone user, and I cordially support this amalgamation, because I think it will be for the benefit of the whole nation—not only for the benefit of the shareholders of the United Company, but I think for the benefit of the whole nation. There is another point also by which I think we shall be benefited—that is, that perhaps the working expenses will be a smaller proportion of the gross receipts. According to the National Telephone Company's accounts—and I suppose we shall have something of the spirit of that Company about the new united Company—their working expenses were about £34,000 against £44,000 of net revenue—that is, their net revenue is about £10,000 more than their expenses. In the case of our Company, I am sorry to say the net revenue is less than the expenditure.

The CHAIRMAN? I did not quite catch what the last speaker said.

The SHAREHOLDER: I think I asked three questions. One was what the Directors will do about the appointment of a Managing Director, and also especially as to his salary, though I forgot to mention that; and further, whether there is likely to be any reduction in the working expenses as compared with the net profit—whether we may in the future look to the profit being considerably more, say 25 per cent. more than the working expenses, or whether it will remain as at present, namely, somewhat less than the working expenses.

The CHAIRMAN: As regards the appointment of a Managing Director, it will be perfectly impossible for me to give any answer to-day. I am here only as Chairman of the United Company, and it will be for the Directors of the new National Company, when you have confirmed these resolutions at your next meeting, to proceed to the appointment of a Managing Director—in fact, of a managing body. I should be very glad to tell you anything I could, but it is impossible to-day. I shall never have the pleasure of meeting you again as Chairman of the United Telephone Company.

A SHAREHOLDER: Yes, once more.

A SHAREHOLDER: We are already the largest shareholders of the National Company, and if we amalgamate we shall still be the largest shareholders in that Company; therefore, any expression of opinion from this meeting ought to have due weight with the Directors of the National Company.

The CHAIRMAN: It shall have due weight, but I cannot answer your question until the new Board meet and decide as to what is to be done. We shall bear in mind what you have said on this and any other points. The same answer must apply to the question about the salary of the Managing Director.

A SHAREHOLDER: It seems to me, as we are settling the new company with Articles of Association for all time, that hardly sufficient attention has been given by the shareholders to the Articles as it is proposed to alter them. It is true that a copy of the proposed alterations has been lying at the offices of our Company, yet I suppose not one-tenth of the shareholders have seen it. Even if they have, it is impossible for them in the space of the few minutes which they could devote to thoroughly digest the alterations. I think, therefore, it is highly desirable that, between now and the special meeting to be convened for passing these three resolutions—[A voice: Confirming them]—these new Articles should be printed and distributed to all the shareholders. We could then come prepared to criticise these alterations. It will settle them for ever, and my suggestion, if acted on, will do away with unpleasantness at future meetings perhaps.

Sir E. H. GALSWORTHY: I think there is a great deal in the observations of the last speaker. At first it would strike one as better—I was going to say fairer, though our Directors could not do anything unfair—had we had a copy of the Articles of Association At the same time, what is proposed is that the Articles of Association shall be those of the new National Company. This is a transfer of this Company to the National Company, and, consequently, you must adopt the Articles of the National Company until you make some alterations in them. Will you tell us whether you are going to adopt the National Company's Articles as they are, or are these Articles, which have been exhibited but which have not been seen, new and fresh?

The CHAIRMAN: They are new and fresh Articles, adapted to the circumstances of the case.

Sir E. GALSWORTHY: Then they are new Articles?

The CHAIRMAN: To a certain extent.

Sir E. GALSWORTHY: Then I think it would have been better had we had a copy of them. Will you, then, please say who are to be the

Digitized by Google

Directors under the new Articles, as that bears on the question put by the gentleman who first raised this point.

A SHAREHOLDER: I may say that I applied for a copy of the proposed Articles of Association and was unable to get them.

A SHAREHOLDER: Is there to be any extra remuneration to the Directors?

The CHAIRMAN: No, there is not. The new Directors will be all the present Directors of the United Company, four of the National Company, and four of the Lancashire and Cheshire Company, and their names are: Messrs. Agnew, Batten, Brand, Bruce, Forbes, Peter Garnett, Heyworth, Col. Jackson, Leyland, Morgan, Parrish, Quilter, Robertson, Sands, and Alderman Thompson.

Sir E. GALSWORTHY: That being so, do I understand that the remuneration of the future Board is limited to £5,000, apart from any interest in the profits, and that the new Board will have power to appoint an Executive?

The CHAIRMAN: Yes; here is the article. Shall I read it?

Sir E. GALSWORTHY: I will take your word for it. That being so, I think this meeting might very well leave to the new Board the questions of who they are to appoint as the executive, and what they are to pay them. There can be no question that the new Board will be—well, I was going to say, a very superior Board to the present. I did not mean that in the sense the meeting has taken it, but a larger Board, and as they are to have some excellent people added to their number it must be a better Board. We might therefore leave these matters to them. We must also bear in mind that it is not what these Directors do in the future with respect to the executive, because what they do can be reviewed by the shareholders in the future. It is quite true that under these Articles of Association they have the power to appoint the executive and to pay them what they think fit. What they do, however, must be reasonable; otherwise the shareholders will alter the Articles of Association. I see the solicitor present, and if I am wrong in what I am saying he will put me right; but if I am right in my view, I think we can well leave these matters in the hands of the Board.

A SHAREHOLDER: We hold a large number of shares in subsidiary companies not embraced in this amalgamation. We hold a very large number of shares in the Telephone Company of Ireland, the Western Counties and South Wales Company, and the South of England Company.

The CHAIRMAN: They are all included in the amalgamation at the market price.

The SHAREHOLDER: That means that the United Telephone Company, to whom those shares at present exclusively belong, and which shares are to a great extent undeveloped, hand them over along with our other assets, and that in future the interest in the development of these shares is participated in by the National and the Lancashire and Cheshire Companies with the United Company, who are at present the sole owners of them.

The CHAIRMAN: That is so.

The SHAREHOLDER: I think it is a very good bargain for the National and for the Lancashire and Cheshire Companies.

Mr. LEYLAND: We have heard views quite the reverse.

The CHAIRMAN put the resolution, and it was adopted. Continuing, he said: The next resolution is—

"*That with the view of giving effect to the above-mentioned agreement, and in order to enable the shares to be allotted thereunder to be distributed among the members of this company, this company be wound up voluntarily under the Companies Acts, and that Mr. Thomas Abercrombie Welton be, and he is hereby, appointed liquidator for the purpose of winding up its affairs and distributing its property.*"

The DEPUTY-CHAIRMAN: I beg to second that.

The CHAIRMAN put it and it was carried. He afterwards proposed the following resolution:—

"*That pursuant to the 161st Section of the Companies Act, 1862, the liquidator be, and he is hereby, authorised to carry the said agreement into effect, and to receive the shares agreed to be allotted thereunder and to distribute the same, together with the shares of the National Telephone Company (Limited) already held by this Company, in specie among the members of this Company.*"

The DEPUTY-CHAIRMAN: I beg to second that resolution.

A SHAREHOLDER: I want to ask the meaning of the words "in specie."

The CHAIRMAN: We have had many inquiries on that point, respecting which I have been astonished. It is a legal phrase, not meaning gold and silver, but in kind.

A SHAREHOLDER: In shares of the National Telephone Company?

The CHAIRMAN: In kind. In shares of the National Telephone Company.

The SOLICITOR: The shares will be distributed in shares, and will not be sold and converted into money.

The CHAIRMAN put the motion, and, having declared it carried, said: That is the business of the day.

Sir E. GALSWORTHY: Before this meeting dissolves there is one duty we have to perform, and I think you will agree with me in regarding it as a duty—that is, to express our opinion upon the services of the Directors during the past year. I am one of those who attended the last meeting, and I heard very considerable discussion. I remember that the Directors were taken to task over all sorts of things. I have been watching the telephone companies from that time to this, and it has always seemed to me, as it must to you, that to bring about this arrangement which has been so unanimously adopted to-day must have given an enormous amount of trouble to the Board. In times past we have admired our friend Mr. Brand, and I admire him very much to-day. He is not only an able and useful Director, but a highly ornamental one as well. I mean that as an absolute fact. I am one of those who think that the Directors have had a very nice thing in getting £11,000 in fees for the last year, but that has come to an end, and I do not begrudge the amount. This is a most complicated matter, as any one can see who examines the accounts of the Company. There is one point that I much regret—that is, the statement of the Chairman that this is the last time that he is going to preside over us. I hope, on the contrary, that we shall see him often, for he is a capital Chairman. I now move—

"*That the best thanks be given to the Directors for their able services and great attention to the interests of the Company.*"

A SHAREHOLDER: May I be allowed to second that? The Directors of this Company have not allowed their own interests to stand in the way in this matter. They have given up for the general benefit the emoluments they enjoyed, which this year amounted to £11,000, and content themselves with the much smaller amount of £5,000 a year, and that is between fifteen of them.

The motion was carried unanimously.

The CHAIRMAN: Sir E. Galsworthy and gentlemen, on behalf of my colleagues and myself, I in the usual way beg to return you our very sincere thanks for the honour you have done us. I must say this is a much pleasanter way of moving a vote of thanks than the way it was done last year, at the fag-end of the meeting, after bullyragging and baiting us to the utmost. We receive your expressions of satisfaction with great gratitude. It has been a most difficult time during this last year, and I can assure you that, whether we have been overpaid or not, I do not think we have been this year, for this matter has occupied a great deal of our time every week. It has been a most difficult thing to bring about, and now that it is brought about I think it is to the satisfaction of all parties concerned. As far as I am concerned myself, if I have the pleasure of presiding over this Company again, or over the greater Company, I shall

always do as much as I can to further your interests. I cannot do more than I have done in the past. I will always endeavour, at any rate, to bring an ornamental presence to the meeting.

The proceedings then terminated.

Lancashire and Cheshire Telephonic Exchange Company (Limited).

Report of the Directors to be presented to the shareholders at the eighth annual ordinary general meeting to be held at the Memorial Hall, Albert-square, Manchester, on Tuesday, the 11th inst., at 11 o'clock.

Revenue.—It will be seen that the accounts only comprise a period of ten months, and the subscriptions and rentals pertaining to that period amount to £80,393. 9s. 5d., as compared with £89,797. 5s. 10d. for the twelve months ended 30th June, 1888. The amount of income carried forward, as representing sums received in advance, for periods extending beyond 30th April, 1889, is £45,569. 10s. 8d.. against £40,377. 3s. 5d. in previous year's balance-sheet.

Dividend.—On the ten months' working the profit is £29,586. 15s. 8d., which, with a credit balance of £1,534. 8s. 4d. remaining from previous account, makes a total of £31,121. 4s. After deducting from this sum interest, bank charges, interest on reserve fund, and the interim dividend paid in March last, there remains a balance of £14,983. 15s. 11d. The Directors now recommend a dividend at the rate of 8½ per cent. per annum for the ten months ended April 30th, 1889, from which will be deducted the dividend already paid in March last (calculated at the rate of 7 per cent. per annum), in respect of the half-year ended December 31st, 1888. This will absorb £13,222. 4s. 6d., and leave a balance of £1,761. 11s. 5d. to carry to the reserve fund.

Progress.—The total number of subscribers on 30th June, 1888, to the various "Exchanges" was 4,103, and of private lines 1,430; this year, at 30th April, the figures were 4,422 and 1,556 respectively.

Notice is also given that the following resolutions will be proposed, which, if passed, will be submitted for confirmation to an extraordinary general meeting as special resolutions:—

(1) "*That the Agreement submitted to this meeting, and expressed to be made between this Company and the National Telephone Company (Limited), for the Amalgamation of the two Companies, by a transfer of the business and property of this Company (with certain exceptions) to the National Telephone Company (Limited), in consideration of shares in that Company be, and the same is, hereby approved.*"

(2) "*That with the view of giving effect to the above-mentioned Agreement, and in order to enable the shares to be allotted thereunder to be distributed among the members of this Company, this Company be wound up voluntarily, under the Companies Acts, and that Thomas Abercrombie Welton be, and he is hereby, appointed liquidator for the purpose of winding up its affairs and distributing its property.*"

(3) "*That pursuant to the 161st section of the Companies' Act, 1862, the liquidator be, and he is hereby, authorised to carry the said Agreement into effect, and to receive the shares agreed to be allotted thereunder, and to distribute the same in specie among the members of this Company.*"

The agreement above referred to, and a print of the Articles of Association, as proposed to be altered, of the National Telephone Company (Limited) may be inspected by members at this Company's office, 38, Faulkner-street, Manchester.

The transfer books of the Company were closed on the the 28th day of May, and will remain closed until the 25th day of June, both days inclusive.

NEW COMPANIES REGISTERED.

THE WOKING ELECTRIC SUPPLY COMPANY (LIMITED).—Registered by Bircham and Co., 46, Parliament-street, S.W., with a capital of £20,000 in £5 shares. Object, the construction of works, machinery and apparatus for lighting streets, &c., by electricity. There shall not be less than three nor more than five directors. The first are H. C. Masterman, E. Stevenson, S. C. Phillips, A. G. Gale and H. S. King. Qualification, £100 stock.

CITY NOTES, &c.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION.—Application has been made to the Stock Exchange Committee to appoint a settling day in and to grant a quotation to the provisional certificates of £75,000 Six per Cent. First Mortgage Debentures of this Corporation.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The Directors of this Company on Wednesday declared an interim dividend of 5s. per share, free of income-tax, for the quarter ended March 31 last, and payable on the 24th inst. The books of the Company will be closed from the 17th to the 22nd inst., both days inclusive. The traffic receipts for the week ended 31st May, 1889, amounted to £3,960.

COMPAGNIE CONTINENTALE EDISON.—At a meeting on April 13 last this Company was authorised to increase its capital from 7,000,000fr. (£280,000) to 15,000,000fr. (£600,000), and the prospectus has been recently advertised on the Continent of an issue of 6,000 new shares of 500fr. each, upon which 250fr. is to be paid up. This issue will raise the capital to 10,000,000fr., or £400,000.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of May were £3,500, as compared with £3,337 in the corresponding month of last year. The receipts for the month of February, estimated at £3,200, realised £3,204.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of May, 1889, amounted to £2,040, as compared with £1,800 last year.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of May, 1889, amounted to £52,704, and to £49,003 in the corresponding period of 1888, or an increase of £3,701.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of May, 1889, were £41,064, as against £40,586 for the same period of 1888.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of May, 1889, amounted to £22,800. From the 1st January to 31st May, 1889, they were £106,800, against, in the corresponding months of 1888 and 1887, £108,400 and £103,520 respectively.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED). The numbers are issued of 72 bonds of £100 each to be paid off on and after June 29, 1889, at the National Bank of Scotland, 37, Nicholas-lane, London, E.C. The bonds are to be left three clear days previously for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended May 31, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,835.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month ended 31st May, 1889, amounted to £6,975.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this Company for the half-month ended May 31, 1889, were £3,078, as compared with £2,978 in the corresponding period last year, showing an increase of £100.

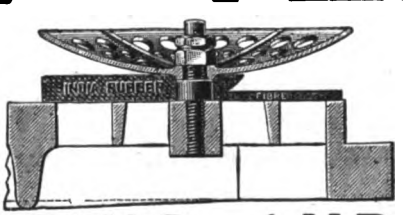
PERSONAL.—Mr. James Staats Forbes has joined the Board of the London Electric Supply Corporation as deputy-chairman.

———Mr. Rankin Kennedy has joined, we understand, the firm of Messrs. Thomas M'Culloch and Sons, at the Vulcan Works, Kilmarnock, whose business will be converted into a limited liability company under the title of Messrs. M'Culloch, Sons and Kennedy (Limited). To their ordinary work of general engineering, as carried on during the past fifty years, the new firm will add that of electrical engineering under the direction of Mr. Kennedy.

———Herr Schuckert, of Nuremberg, &c., announces that his business will for the future be carried on under the title of Schuckert and Co., Kommanditgesellschaft, Nuremberg.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 578.—Vol. XXIII. FRIDAY, JUNE 14, 1889. Price Fourpence.

NOTES.

A communication from Lord Rayleigh and Sir William Thomson in another column raises a note of warning to electrical engineers not too hastily to incur the risk of perpetuating confusion in the terminology of alternating currents. Brevity is good, but lucid and accurate phraseology is better, and our readers will probably concur with the recommendation, for the present at least, to speak always of *period frequency*. Had it not been for the evil example of the French Academy, the practice of dealing with less than a complete vibration would long since have fallen into entire disrepute. But so long as any possibility of misconception remains we must be prepared to make the necessary sacrifice of brevity.

In our report of the meeting of the Physical Society, held on Saturday last, will be found a transcript of a somewhat remarkable lightning photograph, which was obtained by Dr. Hoffert during the great storm of the previous Thursday. It may be taken to confirm the impression, which probably most observers shared, that several successive discharges sometimes followed in the same track at extremely short intervals. Whilst watching this storm from an open heath in the extreme South-West of London, we noticed several flashes which appeared like tangled skeins of flossy silk, the colour being a beautiful red. The red colour was, perhaps, due to the London atmosphere, as all flashes of this colour seemed to be far off in the N.E., whilst the nearer flashes were white or bluish. We may add that Dr. Hoffert tells us that the photograph was taken with a small quarter-plate camera, on an Ilford rapid plate—either the "new" or the "special" plate, it is not quite certain which. The camera was being moved by hand about once to and fro in three-quarter seconds as nearly as could be judged.

We learn that during one of the recent storms a lamp-post at Hampstead was struck, and a side flash, spitting off the horizontal bar with which lamp-posts are usually provided, knocked several bricks out of an adjacent wall. Query—if the owner of the wall could prove that the post was *not well earthed*, would he have his remedy at law? In another case some wooden telegraph-posts are reported to have been demolished. Here, of course, the earth may easily have been bad, but it would be interesting and probably instructive if Mr. Preece would tell us what happened to the wires.

Mr. E. W. Smith's singular device, which Prof. Ayrton has christened by the name of the Shunt Transformer, caused much interest at the Physical on Saturday. The arrangement is so simple that it will be understood at a glance on referring to the diagram on another page. The theory is, of course, a little more complex, but everything depends upon the fact that when an alternating current is divided betwixt two branches, one of high resistance and of small inductance, and the other of high inductance and small resistance, the current phases suffer a relative displacement which in the limit approaches 90 degrees. One result which Mr. Smith succeeded in proving experimentally is that under certain conditions the reading of a dynamometer in the main circuit may *diminish* whilst the lamps actually *increase* in brightness. As Prof. Silvanus Thompson remarked, this sort of thing tends to prove the hollowness of the idea that alternate-current meters can properly be based upon the measurement of coulombs.

Prof. Silvanus Thompson read a Paper at the same meeting, cataloguing eight different methods of suppressing the spark in breaking the circuit of an electro-magnet. Of these the most novel and curious is due to Mr. Langdon-Davies, of Phonopore fame, and consists in winding the magnet with layers of fine wire connected in parallel arc. The resistance and hence the time-constant in the different layers being unequal, at the moment when in one layer the E.M.F. of self-induction is, or would otherwise be, high enough for sparking, it finds a path for discharge along another layer whose time constant is greater. Prof. Thompson spoke only of the application of this principle to magnets of Telegraphic dimensions, but it would seem possible by specially arranging circuits with different time-constants and different current-carrying capacity to extend it to magnets of any size.

We are pleased to be able to announce that Lord Salisbury has consented to receive a deputation on Wednesday next, June 19th, with reference to the proposed Electrical Standardising Laboratory. The deputation will consist of the Earl of Crawford, Lord Rayleigh, Sir William Thomson, and Sir John Lubbock (as Chairman of the London Chamber of Commerce).

The Board of Trade Inquiry held at Dublin last week possessed some very singular features. In this case the Gas

Digitized by Google

Company maintains that by virtue of their Private Act of 1866 they are empowered both to supply electric light and to take up the streets for the purpose of laying mains, and that they therefore require neither Order nor License. It will, perhaps, be remembered that a similar claim set up on behalf of the Liverpool Gas Company in 1883 or 1884 was allowed by the Board of Trade. It was of course admitted that by the Electric Lighting Act of 1883 it was necessary to obtain the sanction of the Board before proceeding to make use of these privileges. Major MARINDIN remarked that he need not concern himself about the precise extent of their existing powers, but that it was his duty to report to the Board of Trade as to the advisability of their being permitted to exercise such powers supposing they did possess them. The Company presented a scheme which contemplated the use of motor generators and secondary batteries for the supply of 2,500 lamps, the capital cost being estimated at from £13,000 to £16,000. Unfortunately, the technical details are not at present before us. Prof. FORBES pronounced the scheme, on the whole, admirable. The Corporation objected *in toto* to the assumptions made by the Gas Company, and is anxious to have its existing powers as to street lighting extended so that it may undertake the supply of electricity for private purposes throughout the City, for which purpose it is proposed to employ the water-power of the Liffey at Islandbridge. The Gas Company had nearly exhausted their present powers of raising capital, whilst the Corporation could borrow to an unlimited extent. To Mr. E. MANVILLE was entrusted the task of exposing the weak points in the scheme of the Gas Company. The Inquiry was over early on the second day.

WE are glad to see that Mr. MASSINGHAM has now publicly announced his intention of proceeding with the Bath Central Lighting Station, in spite of the failure of the public to subscribe the capital for the proposed Limited Liability Company. Mr. MASSINGHAM has secured a magnificent site, almost in the centre of the city, with ample water-power for present purposes and abundant room for future extension, and we have not the slightest doubt that he will carry the venture through to a successful issue.

ALTHOUGH every fifth-rate town in the United States has its complete system of street police signals; here in London the system has only recently been introduced, and that only in a tentative manner and in a single district. We are happy, however, to learn that the authorities have been very favourably impressed with the performance of the system in Islington, where it has now been at work for some six months. Although Islington is not, we believe, one of the most turbulent quarters of the town, yet the signals have already rendered noteworthy service in the arrest of burglars and in summoning aid to secure violent prisoners. It is even said that the knowledge that additional assistance is always within call has already operated to check the tendency to commit assaults upon the police when engaged in the discharge of their duty—a tendency which certain evening papers have done so much to foster. Not the least of the services which such a system is called upon to render is in providing means for the rapid conveyance of injured persons to the hospital. In at least two cases it is believed that the promptitude of the succour thus obtained has been the means of saving life. We shall hope to see the system speedily extended to all parts of the town.

IN reference to the proposed Telephone Convention, we printed in our issue of May 24th (p. 55) a circular which had been issued by Dr. J. MAIER, in which it was stated that the Convention "has been organised by the representatives of the Telephone Companies and the Post Office." The wording of the circular was therefore calculated to lead to the impression that the Convention was in some sense under the official sanction of the Postal Telegraph Department. This, however, is not the case; Mr. W. H. PREECE, although a member of the Committee, is acting solely in his private capacity.

OUR readers will be gratified to learn that the Lords of the Admiralty have consented to exhibit at the forthcoming Electrical Exhibition at Bingley Hall an extensive series of electrical appliances in use in the Navy. The exhibit will include Whitehead torpedoes—in whole and in section—submarine mines, detonators and firing apparatus, submarine lamps and telephones, electric gun-firing appliances, &c. This display cannot fail to add greatly to the interest of the Exhibition. Another object of special interest will be the very early magneto machine built in 1841 by Mr. WOOLRICH at the works of Messrs. PRIME and SON at Birmingham. This machine was long used for electro-plating work, and is without doubt the first electromagnetic machine regularly employed for industrial purposes. An interesting collection of electric-lighting apparatus, including a very early incandescent lamp, is being sent over by Dr. WOODWARD, of Toronto. The contract for erecting the boilers, engines, and other foundations, the orchestra, and the general work connected with transforming Bingley Hall into a fitting home for the Exhibition, has been entrusted to Mr. JOHN PARKES, and the works will be pushed forward with all possible despatch. It is intended to open the Exhibition on Thursday, the 1st of August.

WITH regard to the exhibit from Toronto, of which mention is made above, if all we hear be true the name of Dr. WOODWARD is likely before long to assume some degree of prominence in electrical circles. We have ourselves seen a specification, dated well back in the seventies, in which the learned doctor would appear to have anticipated at least one, possibly two, inventions of the very first importance, and one of which has already been the subject of prolonged litigation. Our readers will naturally be curious to learn how it comes to pass that an inventor of such distinction has "lain low" all these years. Thereby hangs a tale; but for the present we can only reveal the fact that Birmingham may claim the proud distinction of being reckoned the birthplace of this distinguished man; hence there is a certain dramatic fitness in the idea that at Birmingham his achievements should first be brought to the light of day. But of this more anon.

Digitized by Google

Llandudno.—Llandudno pier and pavilion were lighted with the electric light for the first time on Saturday evening.

British Guiana.—The cable between Trinidad and Demerara, which broke down about a fortnight since, is now repaired.

Lowestoft.—The Electric Light Supply Company of Lowestoft have given notice to the Town Council that they intend applying for a Provisional Order.

The West Coast of Africa Cables.—We learn that telegraphic communication has now been extended to Benguela and Mossamedes, on the West Coast of Africa.

The New Telephone Company.—In connection with the above we would direct the attention of those interested to an advertisement which appears in another column of this issue.

Electrical Execution.—A motion has been brought before the Municipal Council of Paris for the adoption of execution by electricity. The matter has been referred to a special committee.

Messrs. Crompton and Co.'s Annual Dinner.—On Friday evening, the 31st ult., the annual dinner of this company to the present and past pupils of the firm was given at the Café Royal, Regent-street. The bill of fare was excellent in every respect, and the arrangements both as regards toasts and music gave much satisfaction and entertainment to the guests, who separated about midnight after spending a most enjoyable evening. The invitations included a goodly number of friends prominently connected with electrical industry and its representatives in the press.

Patents, Designs, and Trade Marks Act.—For the purpose of giving effect to the provisions of the Patents, Designs, and Trade Marks Act, 1888, relating to the registration of patent agents, the Board of Trade, by virtue of the said Act, have issued a set of rules, 23 in number. These rules determine, *inter alia*, the register to be kept and its contents, the registration of persons who were patent agents prior to the passing of the Act, the final qualifying examination for registration, exemptions of pupils, inquiry by Board of Trade before erasure of name from register, and directions as to the hearing of appeals.

Visual Reproduction of Alternate-Current Waves.—Messrs. Siemens and Halske, says the *Bulletin de l'Electricité*, employ the following apparatus for rendering the current phases visible :—A beam of light, which passes through a lens and a small circular opening, is directed on to a mirror fixed to a telephone diaphragm. The beam is reflected on to a revolving polygonal mirror, and thence on to a screen, upon which it describes the current curves on a magnified scale. The forms of current curves of alternating machines are obtained by inserting a telephone as a shunt on the circuit. It will be remembered that Prof. Ayrton recently described a very similar device before the Electrical Engineers.

The Proposed Electric Lighting Company at Bath.—Mr. Massingham has addressed the following letter to the editor of the *Bath Herald*:—

"Sir : From the enthusiasm the electric light aroused in our city, the almost unanimous decision of the Council to adopt it in our streets, and the large number of applications I received from citizens anxious to be supplied with it, I had supposed there was no doubt the Bath Electric Light Company (Limited) would have met with generous support, but, owing to the successful tactics of interested persons, the reverse is the case, and the directors at a recent meeting decided not to adopt the contracts provisionally entered into on behalf of the company. A responsibility therefore attaches to me which I should gladly have shared with my fellow citizens. But, undaunted by the above result, I readily accept the position, and have no hesitation in undertaking single-handed to light an important city like Bath, having not an atom of doubt that as I succeeded at Taunton so shall I succeed here. I intend shortly to lay down plant for public and private lighting, and shall be prepared not only to carry out the contract I have entered into with the Council for lighting the principal streets, but also to supply all private consumers (in the area contracted for) at a price at which the electric light has never hitherto been supplied in any city in the world.

"Bath, June 7, 1889." "H. G. Massingham.

Obituary.—We regret to learn that Mr. John Frederick La Trobe Bateman, F.R.S., V.P.R.C.E., died on Monday morning at Moor Park, Farnham, at the age of 79, after an illness of ten days. He had acquired a high reputation for his scientific attainments, his name having been associated with several of the principal engineering achievements of the day. He supplied Glasgow with water from Loch Katrine, and proposed a scheme to furnish London with water from Lake Bala in Wales. At the time of his death he was engaged in engineering work in connection with docks and gas at Buenos Ayres and water service at Minorca.

Thunderstorms.—On Thursday, the 6th inst., severe thunderstorms occurred in many districts, especially those lying to the South of London. At Bermondsey the tower of the old parish church was struck, and a portion of the plaster ripped off. The chancel of St. Mark's Church, Coburg-road, S.E., was set on fire by what was described by an eye-witness as a ball of fire with a zigzag tail. The roof of St. Giles, Camberwell, was struck, and the Holmsdale Arms, Thornton Heath, was set on fire and partially destroyed. At Partridge Green, a group of farm buildings, known as Broke Wood, was set on fire and almost completely destroyed. Several trees were struck near Denn's Park, and in the Brighton road the tiles on the roof of a workshop were split, the same flash severing a 10-inch beam. The telegraph wire between Horsham and Slinford was cut through. A storm broke with great violence over Steyning ; at Pulborough the iron step of a carriage was cut in two by a flash of lightning. In High-street, New Shoreham, a chimney was split from top to bottom, the bricks falling through the roof of a neighbouring house and doing considerable damage. At Worthing three houses were struck. At Petworth three telegraph poles were struck, one of them being split to pieces. At Stebbing a house was set on fire and a chaff-cutting machine twisted in an extraordinary way. Damage is also reported from Cambridge and the neighbourhood. At Tydd, near Wisbech, a house was struck and burnt to the ground, the same flash killing three horses. The hailstones in many parts of the country were of exceptional size ; at Ipswich they broke the ribbed glass of the Corn Hall, which is over an inch in thickness.

Notes on one of the Recent Thunderstorms.—Prof. Oliver Lodge sends us the following interesting notes on a thunderstorm which occurred in the neighbourhood of Liverpool on the 1st inst. The observations were made by Mr. J. K. Montgomery, a student at University College, Liverpool, and are embodied in a letter to Prof. Lodge :—

"There has just occurred a heavy thunderstorm, and perhaps my unscientific observations of it may to some slight degree be interesting to you. About 3:30 I began to hear the thunder in the distance, so I determined to go out for purposes of "observation." There was not a drop of rain nor a breath of wind, and the air was fearfully hot and close. By this time the thunder was perfectly continuous, though not violent, the dull rumblings being broken by occasional louder bursts. I suppose really it was a series of crashes, but that is the way it presented itself to my mind. I went to the top of Woolton Hill, as that was the most open place about, though perhaps the most dangerous. As soon as I began to get more into the open I saw the flashes, some of them most gloriously beautiful, and curious into the bargain. One of them seemed to describe an irregular arc of a circle, then almost retrace its course, and then flash four or five times right across the sky. In almost all of them I could count four or five times that they crossed the sky backwards and forwards. One or two came almost perfectly straight down, and appeared to strike the road a few yards away from me. I noticed that the perpendicular flashes always seemed single flashes instead of the flash and reflash of the horizontal ones. The thunder was now right overhead, the lightning being seen at intervals of a few seconds. The clouds seemed of a deep grey colour, with broad light copper-coloured edges. Hitherto there had been no rain or wind, but now a sudden gust swept along the road, followed almost immediately by a furious shower of rain. It was not only rain ; there were great blocks of ice, mostly about the size of marbles. I examined them, and observed that they were pretty clear at the edge, but the middle was white and almost opaque. I picked up one block of ice, which was almost quite clear, and about an inch and a-half long by three-quarters of an inch broad and a third of an inch thick. It was of very irregular shape, unlike the rest, which were nearly spherical."

Reception of and Dinner to Prof. Elihu Thomson.—Among the many men of eminent scientific ability and attainments now visiting this country from the United States, one of the most distinguished must be considered to be Prof. Elihu Thom-

Digitized by Google

son, President of the American Institute of Electrical Engineers, member of many other learned societies, and the moving spirit of the Thomson-Houston Electric Company. The close affinity of the Laing, Wharton and Down Construction Syndicate with the Thomson-Houston Company (its *raison d'être* being the extension of the Thomson-Houston system of lighting) rendered it natural that they should seek to welcome the Professor on his arrival in England, and this welcome took the form of a reception and dinner on Wednesday evening last, at the Ship Hotel, Greenwich. Colonel Martindale C.B., late R.E., Chairman of the Finance Committee of the Syndicate, occupied the chair, and was supported by Mr. Percy Westmacott, Dr. Merz, and Mr. Crewdson, Members of the Committee, and by Messrs. Wharton, Down and Davies, the Syndicate's Expert Managers, and Mr. Warine Martindale, the Secretary. Among the guests met to do honour to the Professor were—Sir William Thomson, F.R.S.; Sir Frederick Abel, C.B.; Profs. George Forbes, John Perry, Silvanus Thompson, Ayrton and Hughes; Captains Candee and Holden; Dr. J. A. Fleming; Messrs. J. T. Moulton, Q.C., M.P.; R. W, Wallace, J. T. Bottomley, W. Lant Carpenter, Killingworth Hedges, Musgrave Heaphy, H. G. Massingham, J. F. Meech, W. Lake, C. W. Price, C. E. Spagnioletti, J. W. Swan, W. H. Snell, J. B. Verity, J. E. Wright, &c., &c. Some others of our leading electricians were unable to accept the Syndicate's invitation. The Professor was received on his arrival by a few words of welcome from the Chairman, who was followed by Sir Wm. Thomson, Sir F. Abel, and Mr. Swan. After a brief reply from the Professor the company proceeded to dinner, to which about 46 sat down. The toasts proposed by the Chairman were "The Queen," "The President of the United States," "Professor Elihu Thomson." "Prosperity to the Thomson-Houston System" was given by Dr. Merz, and "Our Guests" by Mr. Wharton. The Professor returned thanks; Mr. Meech, of the Thomson-Houston Company, replied on their behalf, and Mr. Moulton, Q.C., for the guests. The reception and dinner may be taken as an honour justly due to Prof. Elihu Thomson, and as constituting another link in the chain of friendship which is binding ever closer together individuals in the two countries, and thus the two countries themselves.

The Lighting of Reading.—At the meeting of the Reading Town Council on Thursday last week the question of the electric lighting of the streets came up for decision. The report of the Sub-Committee appointed on the 5th ult. stated that they had given consideration to the whole subject of the lighting of the town in view of the termination on June 30 next of the existing contract with the Reading Gas Company; and that they had conferred with the Gas Company and with Messrs. Laing, Wharton and Down, electrical engineers, who are supplying electricity for lighting purposes in Reading. The Gas Company had announced their intention to reduce the price of gas 3d. per 1,000 cubic feet to all consumers, and in any future arrangement with the Company for public lighting the Council would have the benefit of this reduction. The Sub-Committee had also received a proposal for lighting the principal parts of the town by electricity from Messrs. Laing, Wharton and Down, who suggested that the wires for the purpose should be carried overhead, and that the lamp-posts and supports should be supplied by the town. The cost of the gas consumed in the lamps displaced by 30 arc-lamps properly disposed in the places intended to be lighted, they calculated at £455. With respect to the cost of the electric light, they said they were prepared to supply on the following terms, the lamps to be alight for 3,900 hours per annum:—£25 per lamp per annum on a five years' contract, or £24 per lamp per annum on a seven years' contract. Taking £25 as the basis of the cost of the electric light, with 30 lamps, the cost would be £750, against £455 the present estimated cost of the gas; but "ten times the light is given." In other words the cost per candle-power per annum was:—Electric light, 5d.; gas, 41d. The Committee did not make any recommendations in regard to the matter, and the report was adopted. Mr. Field then brought forward a resolution to authorise the sub-committee of the Highways, Streets, and Gas Committee to arrange the terms of a contract with the gas company for the lighting of the public streets upon a specified basis, in which provision was made for the discontinuance of the gas lamps during the whole or any part of the night within any area which the Council might determine to light by means of electricity. The resolution was approved. Mr. Dodd next proposed—"That it is advisable that arrangements should be made, as soon as practicable, for lighting by electricity throughout the whole night such a district as it may be possible to light satisfactorily with 30 electric lamps, and that the Highways, Streets, and Public Lights and Gas Committee be authorised, subject to the approval of the Council, to arrange with Messrs. Laing, Wharton and Down, the electrical engineers, accordingly." He remarked that he had formed the opinion that the electric light recently shown in the town was very desirable indeed for public lighting, and the sooner they took into consideration the lighting of the town by this means the better. The motion having been seconded, the question was fully debated, and, in the end, the resolution was carried by 14 votes to 9.

Electric Launches on the River.—We take the following from a recent article in the *Daily News*:—"Talking of steam launches, their day is undoubtedly fast drawing to an end, so far at least as the upper Thames is concerned. If any one doubts this he has only to go and inspect the 'Ray Mead,' lying out in front of the Ray Mead Hotel, just above Maidenhead. She is not yet certified by the Board of Trade. Her owner duly applied for a certificate, and received the usual form to be filled up, giving full particulars of her engines and boilers, and the names of those who made them, what pressure they were designed for, and so forth. The only reply that could be given was that there were no engines and no boilers on board, and though some little time has elapsed since this answer was transmitted nothing further has been heard of the matter. Who can say what putting together of heads and grave deliberation this knotty point may not have given rise to in Whitehall? How to certify a vessel the boilers of which might possibly blow up in spite of the best precautions would be easy; but how to certify when there are no boilers at all may, no doubt, form a very moot point for the Circumlocution Office. However, no doubt it will be settled one of these days, and the 'Ray Mead' will be free to take on board her 60 passengers and set out on her travels. She is an absolutely ideal craft for the Thames. She is built of Burmese teak; she is 60ft. long and 11ft. in the beam; is daintily fitted up with the electric light, and stained glass and brass fittings, and yellow curtains that harmonise very prettily with the rich brown of her timber. All her motive-power is stowed away under the floor of the cabin, and the switches and the rudder-wheel by which she is navigated are under the hand of one man up over the cabin. Messrs. Immisch and Co. have supplied the motors, and they claim that she will run for twenty hours on the stream at seven miles an hour, which is the maximum allowed by the Conservancy regulations, and she can be fully charged in four hours and a-half, which, of course, may be done during the night. The difficulty in the way of electric launches on the Thames hitherto has been this matter of charging among others. This is now disposed of. Messrs. Immisch and Co. have established charging stations at Richmond, Hampton, Staines, Maidenhead, Henley, Reading, Wallingford, and Oxford; and they have, besides these, two self-propelling stations ready to move to any point on the river at which there may be special need for them. Ten thousand pounds, it is said, has been laid out in this electric-charging scheme for the Thames, and one result is that four electric launches are now afloat on the upper river, and all hands are at the pump to get five more completed to be ready for Henley. These are in addition to the 'Ray Mead' just described, which is certainly the most beautiful little craft of the kind ever yet constructed. It is said that with all her heavy accumulators, and 60 people on board, she draws only two feet of water, and owing to her small propeller—necessarily small in order to get the best possible work out of her motor—and her excellent lines she makes no more wash than a randan. Electric boats were barely represented last year at Henley; this year it is expected that there will be about a dozen launches. This affords rather a striking indication of the rapidity with which the motive-power of electricity is finding practical application.'

THE FUNCTION OF THE CONDENSER IN AN INDUCTION COIL.

BY DR. OLIVER LODGE.

Doubtless many persons have written out a theory of the coil condenser at some time or other, either for their own edification or for that of their students, without regarding it as worth publishing.

Since the subject seems to be of interest just now, I may transcribe my working of the case, though I do not suppose it differs essentially from that of Mr. Boys, nor do I see that his differs very essentially from Dr. Fleming's. Nothing can be clearer than Mr. Boys' letter. Dr. Fleming's article is perhaps rather less simple, partly because he has treated the case of a closed secondary circuit.

The whole object of the break is to stop the primary current as rapidly as possible. If M is the coefficient of mutual induction between primary and secondary, and if x is the current at any instant in the primary, the E.M.F. developed in the secondary, while its terminals are too far separated to give a spark, is $M\frac{dx}{dt}$. This quantity, therefore, determines the maximum length of spark attainable. If the secondary circuit is closed the self-induction of the secondary and the reaction of its current on the primary must be taken into account (the effective self-induction of the primary being reduced from L to $L-\frac{M^2}{N}$), while, if it is only partially closed, so as to permit a spark across an air gap, the conditions are too complicated to treat with complete accuracy, because of the varying resistance of the spark.

The case of a quite closed secondary offers no special difficulty, but it is an unusual case in practice, except when the primary current is supplied by an alternating machine; in which case there is no break, and no condenser is of any use. I will consider, therefore, only the case when the secondary terminals are pulled far apart so as to get the longest possible spark.

Breaking the primary circuit consists in separating two metal contacts so as to introduce an insulating film or partition. The air film so introduced is easily broken by the electro-magnetic momentum, and the current, therefore, prolongs itself, and stops more or less gradually, even though the contact pieces are knocked asunder with a hammer.

Much depends, however, on the way the break is made; anything of the nature of a scrape or drag is bad. Perpendicular separation of hard surfaces is best, and if they are separated by the impact of a bullet considerable suddenness may be attained. Still better if the insulating partition instead of being air i alcohol, or some stronger dielectric not so easily burst as an air film. This, I expect, is the main advantage of mercury breaks, viz., that the surfaces are immersed in alcohol. If the alcohol were put under great pressure, so as to be driven between the contact-breaker terminals more quickly than by merely atmospheric pressure, still further improvement might be possible.

But the most sudden way of stopping a current by direct separation of contact pieces, is to effect the break between the poles of a powerful magnet. The extra current then gets blown out with a bang, and the thereby-induced secondary flash is often of surprising length without the use of any condenser at all.

None of these ways can, however, really stop the current quite suddenly, any more than a stream of water can be stopped quite suddenly by the sudden closing of a tap. Moreover, any attempt at sudden stoppage must be accompanied with violence. But, if an elastic piston or recoil spring is provided, the energy of the current instead of being rapidly dissipated may be stored, and the stored energy may be used to propel it backward immediately afterwards. It is like the difference between stopping a truck by a brake and stopping it by fixed elastic buffers. Suitable spring buffers may be capable of causing a greater acceleration at some part of the recoil than any brake which could be applied, and it may act with less violence.

A condenser is the electric analogue of the spring buffer; it receives the momentum of the electric currents, stores it, and under favourable circumstances gives it back—not only stopping but reversing the current.

If it succeeds in checking the primary spark altogether, the current will be reversed, and re-reversed several times; but this seldom if ever happens. A very large condenser seems to be necessary to permit the current to flow unimpeded until the break pieces get quite beyond striking distance; and such a condenser, being analogous to a long weak spring, would not give a very effective recoil. It seems better to use a moderate-sized condenser, *i.e.*, a stiffish spring, so as to enable the contact pieces to separate by an appreciable interval, and to dissipate the rest of the current energy by the obstruction of the by-that-time introduced insulating layer.

The more rapidly the contact pieces are mechanically separated, the less capacity of condenser is necessary.

The ideal arrangement would be to use a very small condenser and to separate the parts with great rapidity.

It may also be remarked that small self-induction in the primary is an advantage, as diminishing the spark at break. Instead of a great number of turns and a battery of high E.M.F., it is far better to use a stout thick primary of few turns, and to send a powerful current through it by a large storage battery of low E.M.F. Since closing the secondary *reduces* the virtual self-induction of the primary, it follows that if a satisfactory break can be made with secondary circuit open, it will be still easier when secondary sparks are permitted.

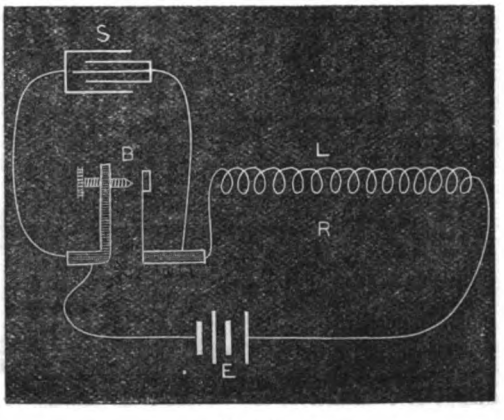

FIG. 1

The investigation of what happens in the primary when the secondary circuit is open is simple enough, and is as follows:—

Let a current, x, be flowing in primary, consider what happens when break occurs at B. The initial condition is, condenser uncharged, and $x=\frac{E}{R}$. Directly the break occurs the condenser begins to charge and the primary to stop. The final condition is, $x=0$, and condenser charged with quantity

$$Q=\int_0^\infty x\,dt=ES.$$

Now the equation to the current during the change from initial to final condition, provided no spark is permitted at B, is given by

$$E-Rx-L\frac{dx}{dt}=\frac{1}{S}\int_0^t x\,dt,$$

which, taking into account initial and final conditions, is equivalent to

$$x=\frac{E}{R}\,e^{-m}\left(\cos n\,t+\frac{m}{n}\sin n\,t\right),$$

where $$m=\frac{R}{2L}\text{ and }n^2=\frac{1}{LS}-m^2.$$

The E.M.F. excited in the secondary at any instant is

$$-M\frac{dx}{dt}=\frac{ME}{RnLS}\,e^{-m}\sin n\,t.$$

Digitized by Google

This begins with the value 0, showing that at the first instant after break the primary flows on with undiminished strength, charging the condenser, and thus affording time for the break to get fairly thorough, so as to avoid a spark more or less completely. It has its greatest value at a time T after break, such that

$$\tan n\,T = \frac{n}{m}.$$

It will be convenient to call the angle whose tangent is $\frac{n}{m}$, θ;

so that

$$T = \frac{\theta}{n}.$$

The angle θ is in most cases approximately a right angle unless S is very big.

The maximum value of the E.M.F. thus induced is obtained by inserting this value instead of t, which gives

$$-M\left(\frac{dx}{dt}\right)_{max} = \frac{ME}{R\sqrt{(LS)}}\,e^{-\frac{m\theta}{n}}.$$

Now, if it were possible for n to be negative, the above expression could be given a maximum value by satisfying the condition

$$\tan^2\theta = \frac{\tan\theta - \theta}{\tan\theta + \theta},$$

the solution of which is $\theta = 111^\circ\ 1'\ 52''$,

or

$$\frac{n}{m} = -2{\cdot}6024.$$

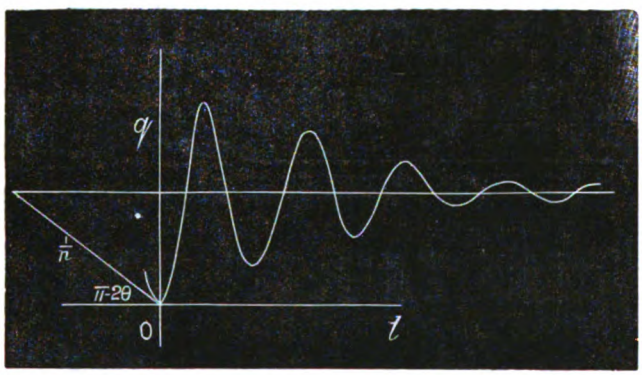

FIG. 2.--Charge of condenser at any instant if no primary or secondary spark occurs.

But as this is physically impossible, the next best thing is for n to be very big—that is, for S and L to be as small as convenient.

L cannot, indeed, be very small, because one factor of it is involved in M; but inasmuch as $\frac{M}{L} = \frac{N\,N'}{N^2} = \frac{N'}{N}$ approximately (the N referring to number of turns of wire), it is manifestly well to have the secondary with the greatest possible number of turns and the primary with very few.

As to S, the capacity of the condenser, it should be as small as is consistent with a stoppage of the break spark; or since it is perhaps not advisable to stop the spark altogether, some kind of compromise must be arrived at, which cannot be gone into much further without specific information as to the rate of separation of the contact pieces.

This much, however, may be said: the difference of potential between the contact-breaker terminals at any instant is proportional to the charge by that time accumulated in the condenser, being equal to $\frac{q}{S}$, where

$$q = \int_0 x\,dt = \frac{1}{n}\left\{\sin 2\theta - e^{-mt}\sin(2\theta + nt)\right\},$$

θ having the same meaning as before, viz., the angle whose tangent is $\frac{n}{m}$.

Fig. 2 is a curve with the general characteristics of this diagram.

If a spark at break is to be avoided, the parts must separate faster than this rapid rise of potential can, so to speak, catch them up, by becoming strong enough to burst the air film they have succeeded in interposing in its way. The charge of the condenser reaches its maximum in a time $\frac{\pi - \theta}{n}$, or practically in a time $\frac{1}{2}\pi\sqrt{(LS)}$. If the terminals can get beyond striking distance within this time they are safe, and there can be no primary spark. But this time is terribly short. For instance, with a condenser $\frac{1}{20}$ microfarad capacity and a primary coil of $\frac{1}{50}$ secohm self-induction, this time is the twenty-thousandth part of a second. Self-induction between break and condenser is wholly bad; the condenser should be connected up as directly as possible.

REVIEWS.

Popular Lectures and Addresses. By Sir WILLIAM THOMSON. In three volumes—Vol. I., "Constitution of Matter." (Macmillan and Co., 1889.)

It appears from the preface that the collecting together in a convenient and accessible form of Sir W. Thomson's Popular Lectures is due in the first place to a suggestion from Mr. Lockyer that the lecture on "Capillarity," which first appeared in the pages of *Nature*, should be re-issued as a separate volume, with the addition of some other matter connected with the subject. Fortunately for the wide circle of readers who will, we trust, make acquaintance with the pages of this charming book, Sir William decided to extend the scope of the work proposed by Mr. Lockyer by issuing a short series of volumes containing such of his more important lectures and addresses as would not find a fitting place in the reprint of his mathematical and physical papers, and they will feel themselves considerably indebted to Mr. Lockyer for his share in procuring for them a great intellectual treat, or rather a series of intellectual treats, for, taking the present volume alone, the Bill of Fare provided is not one which can be assimilated at a single sitting.

Sir W. Thomson's mathematical papers have a charm for those who are able to follow him in his explorations into some of the most obscure and intricate of Nature's pathways, guided by the bright but somewhat overpowering light of mathematical analysis. Sir William's purely scientific work, whether mathematical or experimental, excites our admiration by its massive power; and this applies more especially to the former division of his work, for, while his analysis is often somewhat lacking in elegance and polish, it always goes straight to the heart of a difficulty, and, instead of skilfully avoiding or circumventing it, sweeps it by main force out of the path and exposes the hidden treasures which lay beneath the apparently unsurmountable obstacle. Even in his popular lectures the same sense of power is present with us. Instead of feeling ourselves skimming lightly over the surface of the great sea of scientific knowledge, and obtaining, without much effort on our part, faint and transient glimpses of a distant scene, we feel ourselves led forward by the strong helping hand of a skilled guide over some of the most rugged of Nature's paths, where, in spite of the help extended to us, we have to exert our own powers to the utmost lest we should fall behind. The first lecture in the book, "On Capillary Attraction," is one of the best examples that could be found of Sir W. Thomson's power of carrying his reader or his hearer along with him, and letting him see, as it were, the actual working of his brain.

The author tells us that in these lectures he has tried to lay bare the principles of this difficult subject to "those people who fancy that they cannot understand sextuple integrals," a class which is perhaps more numerous than he imagines. He has certainly succeeded in making the subject comprehensible to those readers who, though unable from want of technical knowledge of the higher mathematical analysis to follow the ordinary expositions, are yet able to follow a course of sustained scientific reasoning.

Digitized by Google

This lecture is one which will be of the greatest assistance even to mathematicians who are well acquainted with the analysis of the subject, for the mathematical scaffolding by which we succeed in scaling heights which would be otherwise inaccessible always obscures some portion of the view, which only opens itself out to its fullest extent when some great master-mind, after having used the scaffolding for the first ascent, has succeeded, by the aid of the closer view thus obtained of the difficulties of the way, in opening up an independent path to the summit. The lecture on "Electrical Units of Measurement," delivered at the Institution of Civil Engineers in 1883, and that on "Electrical Measurement," delivered in connection with the Loan Collection of Scientific Apparatus, at South Kensington, in 1876, are the two which will be of most direct interest to our readers, and we must earnestly recommend those who have not already done so to read, mark, learn, and inwardly digest them. There are very few electricians, even though fairly well versed in the principles of the modern absolute system of electrical measurement, who will not find their views on the subject considerably widened and deepened by the careful study of what Sir W. Thomson has to say about them in these pages.

The history of the development of electrical measurement affords one of the very best examples of the value of scientific theory, and the reader, be he a scientific electrician or a practical engineer, who has learnt this lesson, will treat with equal contempt the sneers of the "transcendental theoriser who builds his elaborate structures upon utterly inadequate experimental foundations, or upon the shifting sand of unsupported hypothesis" and the ignorant drivelling of the rule-of-thumb man, who, dimly conscious of the fact that his brain-power is not equal to the task of becoming a scientific engineer, fears that his bread will be taken out of his mouth by his more highly gifted competitors, and, like the fox who had lost his tail, tries to persuade all the other foxes that tails are inconvenient and unnecessary appendages, and had better be cut off.

The lecture which bears the title, "Steps towards a Kinetic Theory of Matter," will be read with exceptional interest by those of our readers who were fortunate enough to hear Sir William's inaugural address this session to the Institution of Electrical Engineers, for here they will find developed in somewhat more detailed form a theory which was almost too briefly touched upon in the inaugural address to enable most of those present, to whom the subject was new, to obtain a very clear grasp of it, in spite of the interesting gyrostatic experiments by which it was illustrated.

The lecture on the "Six Gateways of Knowledge" deals with our means of perception of the external world. The six gateways consist of the well-known five senses, together with the sense of touch, divided into two senses, viz., the muscular sense, or the sense of force, and the sense of heat, a distinction which certainly appears to be reasonable, for the sensation of heat is no more like the sensation caused by the action of force than is that of light. In addition to the lectures we have especially noticed, the book contains others of the greatest interest on "The Size of Atoms," on the "Wave Theory of Light," and on "The Sun's Heat," together with brief abstracts of lectures on "Elasticity Viewed as Possibly a Mode of Motion," and on Maxwell's "Sorting Demon."

ELEMENTARY THEORY OF THE "ARMATURE REACTION" TYPE.*

Alternate-Current Motors.

BY M. W. RECHNIEWSKI

If we take an ordinary continuous-current dynamo or motor, short-circuit the armature through the brushes, place the latter at an angle of 45deg. with the magnetic axis A B (Fig. 1), and send an alternating current through the field magnets, it is well known that it will work as a motor. The armature will not start from rest, but it rotates in whichever direction it may chance to have been started with a velocity which tends continuously to increase. The couple increases, moreover, with the velocity; hence it is so far clear that a practicable motor can be constructed upon this basis. But in order that we may be enabled to choose the best proportions, and that we may understand what can reasonably be expected from this type of apparatus, it will be necessary to study the manner in which the couple is produced. In this case, as in that of the transformer, we shall assume that the alternating current follows the sine law. We will divide the armature (Fig. 1) into four regions, *a b*, *b c*, *c d*, and *a d*. Now, when the mag-

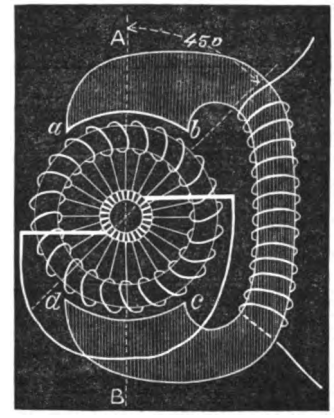

FIG. 1

netic induction varies in the system an electromotive force is, of course, produced in each turn of the armature wire. In the regions *a b* and *c d* the E.M.F.s thus generated are equal and opposite on either side of the magnetic axis, and mutually cancel one another. On the other hand, in the parts *b c* and *a d* the E.M.F.s generated act together to produce a difference of potential at the brushes, and an (alternating) current, therefore, traverses the circuit of the armature. Returning to the

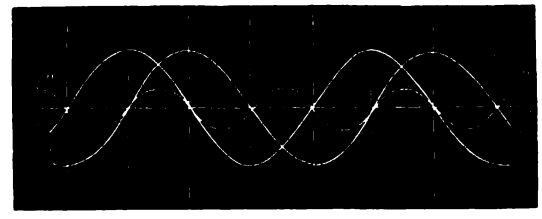

FIG. 2.

regions *a b* and *c d*, we see that the couple produced by the current in the coils and the alternating field tends to cause rapidly reversed impulses of equal extent and duration; consequently this contributes nothing to the rotation of the armature, and the machine cannot start of itself.

In Fig. 2 let *s* represent the curve of magnetic induction due to the field, then *s'*, the curve of current in the armature, will be displaced 90deg., or, in other words, will have a lag of a

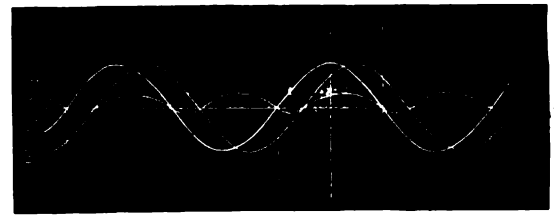

FIG 3

quarter-period.* The couple produced, which will be simultaneously proportional both to the current and to the induction (being zero when either *s* or *s'* is zero), may be represented by the curve *s''*, in which the areas cross-hatched above and below the axis represent the effect in either direction respectively.

Let us now suppose that the armature is already in movement. This introduces a new factor due to the E.M.F. gene-

* Extracted from an article in *La Lumière Electrique*, May 18th, 1889.

* The author here neglects the effect of self-induction in the armature.

Digitized by Google

rated in the coils by their own displacement in the magnetic field. This new E.M.F. is evidently proportionate to the field [and to the speed of rotation] and its phase is necessarily identical with that of the field; it can, therefore, be represented by s in Fig. 2 and Fig. 3. The current in the armature is now due to the combination of these two E.M.F.s which differ in phase, and it may be represented by a sinusoid s''' (Fig. 3) displaced by a certain arc ϕ from that of the field itself. The dynamic couple, being at each instant proportional to the product of the ordinates ss''', will now be represented by a curve, s^1, in which the areas enclosed upon one side of the axis are greater than those upon the other side [the difference depending, of course, upon the value of the lag, ϕ, which is really a very complex function]. It is, moreover, easy to show that the effect is greater in the same direction as that of the previously existing rotation; consequently the speed of the armature tends continuously to increase, and it can be made to do work.

The objection of having to start the motor by hand may be overcome by introducing into the armature circuit an inductive resistance sufficient to establish the required lag, which can be withdrawn as soon as the machine has commenced to run.

BOARD OF TRADE INQUIRY ON THE ELECTRIC LIGHTING OF THE CITY OF DUBLIN.

On the 6th inst. Major F. A. Marindin, R.E., one of the Inspectors of the Board of Trade, opened an inquiry in Dublin to hear an application by the Alliance and Consumers' Gas Company for permission to open certain streets in the city for the purpose of laying electric lighting cables for lighting of private houses. The Gas Company contended that under their Acts of Parliament they required no License and no other permission than the one they sought. The Corporation opposed the application.

Messrs. George Wright, Q.C., and Alex. Holmes (instructed by Messrs. D. and T. Fitzgerald) appeared for the Gas Company.

The Right Hon. S. Walker, Q.C., and Mr. Richard Adams (instructed by Mr. J. MacSheehy) appeared for the Corporation.

The INSPECTOR said this inquiry was of a novel character. The ordinary inquiry was where a company was seeking by means of a Provisional Order to get power to supply electricity or water where the local authority withheld its consent. In this case the company was moving the Board of Trade to exercise certain powers which they said they had under their Acts, but he should treat it as if it were an ordinary case, and ask the Gas Company to give him any reasons they could why the Board of Trade should exercise those powers. Of course he had nothing to do with the legal interpretations of these sections.

Mr. WALKER said he wished to guard himself against being taken as assenting to the proposition of the Gas Company. This inquiry proceeded on the assumption that they had a statutory authority which enabled them to do everything except open the streets. The contention of the Corporation was that the Gas Company had no such power, and if they had it they should obtain a License or a Provisional Order under the Act of 1882. Even if the Board of Trade gave the company the right now claimed, the Corporation could proceed against them hereafter by injunction, and would do so. He was, therefore, to be taken as protesting against the inquiry.

The INSPECTOR: All I have to inquire into is whether, supposing they have the right, it is desirable they should exercise it.

Mr. GEORGE WRIGHT said the Act of 1866 was the one by which the Alliance and Dublin Consumers' Gas Company was formed for the purpose of "making and supplying gas and other improved means of lighting for public and private purposes;" and it had always been maintained by the company that under that they had the power of supplying electric light. In 1883 the company went to Parliament to get powers to raise a capital of £286,000. About that time the company purchased the plant of the Dublin Electric Lighting Company, and had been since supplying electric light to a number of firms in the city, to the great satisfaction of the public, their right to do so never having been questioned. It had been supplied by overhead wires, but to that system there were many obvious objections, and it was necessary that the company should have power to open up the streets and lay them underground. The Gas Company had power to open the streets for all the purposes of their acts; and if the legal position of the company was right, that they had the power to supply electric light also, it would follow, and they had been so advised by eminent counsel, that they had the same power, or at all events up to the Act of 1883, to open up the streets for the purpose of laying these electric wires. By the Act of 1883 a certain restriction was imposed on them which made this inquiry necessary. That restriction did not take away from them the power to open up the streets, but said that they should not be at liberty to do so without the permission of the Board of Trade, who might impose such conditions for the public safety as to them might seem reasonable. To that the company had no objection. The Corporation of Dublin had already got a License for public lighting, and had power to open the streets wherever they liked, and the Gas Company only asked the same permission for private lighting. The scheme the company brought forward was this: Of old capital there remained £13,000—that was of the capital raised in 1866; that capital was not tied up in any way, not subject to any restrictions, and was now applicable to any scheme of electric lighting that they might devise. They had a further sum of capital under the Act of 1883 of £383,000; that they could not touch without getting the sanction of the Board of Trade, for the 25th Section of that Act provided that it should not be applied to the supply of electricity without the sanction of the Board of Trade. It might be that in the future they would ask for that sanction, but in the present application they did not. As to any excess in the present estimate over the £13,000 capital there would be no difficulty about raising it. As to the works themselves, the area was a rather populous, busy, and wealthy part of the town, where there was a very great demand for electric lighting. The citizens of Dublin, who were more interested in this matter than anyone else, were of opinion that it was better that all this should not be in the hands of any one company, whether that was the Gas Company or the Corporation. They had had numerous applications from persons living within the proposed area to supply them, but they could not do so at present without risk by the system of overhead wires.

The INSPECTOR: Do you contend that you are empowered under your Act to supply electric light to the whole of these thirteen townships?

Mr. WRIGHT: Certainly, and the whole metropolitan area.

Mr. ARTHUR PORTE, Electrical Engineer, said that the Gas Company proposed to use secondary batteries combined in sub-stations. In the area proposed to be taken in there were about 600 houses, a large number of public institutions and clubs. Within the last year they had received applications from 34 or 35 separate houses for a supply of the electric light. The scheme would cost from £13,000 to £16,000.

To Mr. Adams—There was a loss of about £100 a year at present on electric lighting. The Electric Lighting Company charged 5d. an hour for an arc lamp, the Gas Company charged 8d., but in one case where they had a large consumer they charged less; for incandescent lights the Electric Company proposed to charge ½d. an hour, the Gas Company charged 1d. He had no objection to the Corporation and the Gas Company operating in the same area.

Do you agree with this: "Represent the undesirability or serious danger of rival electric wire systems running underground amidst gas pipes, and that the inevitable consequence will be defective insulation on the one hand and leakage from gas mains on the other if running concurrently?"—There should be no difficulty if they are well laid.

Mr. WRIGHT asked where the quotation was taken from.

Mr. ADAMS said from a petition by Mr. Pembroke Stephens and Mr. A. M. Sullivan on behalf of the Gas Company against an electric lighting scheme.

Prof. G. FORBES, F.R.S., deposed he had examined the scheme prepared by Mr. Porte; he believed the estimate was very closely accurate. The plan was a very good one indeed, and would work very well; it would be a most thorough and satisfactory working of the district, very much more so than one was accustomed to see.

Mr. HOLMES: What is your opinion generally as to competition in these matters of electric light?—I do not like monopoly. Undoubtedly where competition comes in consumers are better satisfied in a great number of ways, not only as to price but also as to having their complaints attended to, and so forth.

Cross-examined by Mr. ADAMS: Witness said the continuous-current motors had been used largely before, and distribution from a central station had also been used largely; but the two in combination, as proposed here, had not been used before on so large a scale. Several other witnesses were examined on behalf of the Gas Company, and then

Mr. WALKER opened the case for the Corporation. There was nothing in any Act of the Gas Company to authorise them to supply electric light without coming to the Board of Trade in the usual way. When the Corporation applied for a public License the Gas Company brought in objections, but they ran away before the inquiry. One of the heads of their objection was, "It is the intention of your memorialists to apply this year for a Provisional Order under the Electric Lighting Act, 1882, to obtain the necessary powers." Therefore they had it under their own hand that they were then about to do what they were bound to do, namely, proceed by Provisional Order; but because they knew that the Corporation would not consent to a License they had not done so. And now they tried to avoid it by saying that they had power under the Act of 1866. The Corporation were the local authority for the whole city, and had already obtained a License for public lighting; they intended to proceed and obtain a License for private lighting, and they had unlimited powers of borrowing. Now, what was the position of the Gas Company? They had exhausted all the capital which might have been applied under the previous Acts—if they were right—to electricity, and they now intended to borrow under an Act which preveuted them applying any of the money to electricity, and they would put that capital in place of the old. It was absurd to suppose that one farthing of that capital could be legally applied to the purposes of electricity. It was an extraordinary proposition that a gas company should, out of the city, pick out this little bit of residential portion and apply a limited capital of £12,000 to it, leaving the less wealthy district to be supplied by the local authority. Would the Board of Trade sanction a scheme which never could go beyond that limited area? Was it to be supposed that the company would run this electric light against the gas supply; and, having on one hand a gas supply yielding 10½ per cent., and on the other this novel experiment of electric light, was it not obvious that their object was to smother the electric light in its cradle? He submitted that the application was wholly illegal and should be refused.

Mr. EDWARD MANVILLE, examined by Mr. ADAMS, stated that he was an electrical engineer. He knew the part of the city proposed to be lighted by electricity by the Gas Company, and he was aware that it included the principal public buildings of Dublin—Trinity College, the Museums, the National Gallery, the principal hotels and clubs. He had heard it stated that there were 600 houses in that particular locality, and, taking it on an average of 40 per house, it would require 24,000 lamps to

Digitized by Google

light it. According to the provision made at the distributing station, the number of lamps that could be supplied under this scheme would be 2,500, and in case of accident there was no proper provision for the duplication of machinery.

The Right Hon. the LORD MAYOR, M.P., examined by Mr. ADAMS, said: The Corporation had undertaken and carried out a scheme for supplying the city with water, and that scheme had given great satisfaction to the citizens of all classes, and he did not believe there was a city in the world which, in point of the price and amount of supply of water, was in a better position than Dublin. The Corporation administered a sum of £300,000 a year, and, though the accounts were audited by an auditor of the Local Government Board, such a thing as a surcharge was unknown. The present position of the lighting of the city was unsatisfactory, and there was a strong and earnest desire that some steps should be taken to improve it. The present proposal of the Gas Company he regarded as one confined to the residential part of the city, and in so far a class proposal. The effect of such a scheme would be to take out the oyster and leave the shell, and to confine the electric lighting to fashionable quarters.

The INSPECTOR asked what powers the Corporation proposed to take to light the city with electric light?

The LORD MAYOR said they proposed that there should be compulsory powers to light a certain area, and then that the other areas of the city should be lighted on requisition of the inhabitants in particular districts.

Mr. THOMAS MAYNE, M.P., was next examined by Mr. ADAMS. He stated that he was a director of the Electric Lighting Company of Dublin. He believed it was the first company that went into electric lighting on a commercial basis without stock-jobbing arrangements. They thought the plant they bought the best at the time, but before they went into liquidation they found that it was not. It was necessary to buy new plant and call up new capital for the purpose, and, as there was a scare at the time in electrical lighting matters, the shareholders got frightened, and thought it better to go into liquidation. He thought if the company continued they would make a fair profit. As it was the plant was sold by the liquidator to the Gas Company for £3,000. They only charged 5d. per arc lamp, whereas the Gas Company charged 8d. per lamp.

Mr. JOHN BEVERIDGE, Town Clerk, examined by Mr. ADAMS, said the Town Council since 1881, when some valuable property came into the hands of the Corporation, had taken the matter of electric lighting for the city into their consideration. There was water-power on that property, which was situate at Island Bridge, and it was thought this water-power might be utilised for the public lighting of the city with electricity. The Corporation had large unexhausted borrowing powers, and these powers might be used in this matter. Some time ago they got a license for the public lighting of the city, and since then they took into consideration the question of private lighting. In regard to private lighting the Corporation proposed to leave it optional with the contractor to avail himself of the Island Bridge site, or any other site that would prove more economical.

The Inquiry was then adjorned to the following day.

FRIDAY, JUNE 7.

On the resumption of the Inquiry,

Mr. ADAMS replied for the Corporation. This application was a clear attempt to evade the law, and by a short cut to get rid of the precautions which Parliament had imposed upon them. Their contention was that in the Act of 1866 the words "improved means of lighting" included electricity. But when they promoted a Bill in 1879 they put in words defining "improved means of lighting" as including electricity, but Parliament struck them out, thus showing that they had not these powers. The interest of the Corporation was to develop the electric light in every possible way, and to try and provide the citizens with a better and cheaper light than gas, which had the monopoly. It would be a monopoly if all the means of lighting were in the hands of the Gas Company. The interest of the Gas Company was to stifle and strangle the electric light. They were now in the happiest position in which a company could be. The shareholders were drawing 10 per cent., the directors received handsome remunerations, and the officers princely salaries, and they regarded the electric light as a troublesome intruder on this Paradise. If the electric light were given to the Corporation they would nurse it and cherish it in the interests of the citizens, and make it a giant. If it were given to the Gas Company they might fondle the baby in public, but in private they would pinch it and starve it, and in the end they would wring its neck, and bury it in the coal-hole. At the end of 23 years they had only nine customers, and they would not have moved now only that the Corporation had taken steps to procure a private licence. Then as to the estimate, there was £16,000 worth of work to be done, and the company had £10,000 with which to do it. It would be a monstrous thing to allow this Gas Company to cripple the Corporation by cutting out of the city this prosperous and important bit. Weight must be given to the opinion of the local authority, which really ought to be supreme in these matters, and whose supremacy had received on a recent occasion Parliamentary sanction. The Corporation, representing a quarter of a million citizens, had unanimously decided to oppose the project, and counsel asked the Board of Trade to refuse it as not being a *bonâ fide* but a bogus application.

Mr. HOLMES replied. He did not come there to impugn the character of the Corporation or their capability to carry out this work, but he believed the Gas Company had shown that they were equally competent, and the charges which Mr. Adams had made against them ought not to be made without evidence. If the Gas Company were wrong in law, the moment they attempted to open the streets the Corporation could apply to the Courts of Law for an injunction or a mandamus; and they ought not to have appeared at this Inquiry at all if they believed they had the law on their side. The Gas Company said there was a demand in the city of Dublin for the electric light, and they had shown it by the number of applications signed by eminent professional and business men which they had produced. The company said they were capable of meeting that demand by the scheme they had produced. With regard to the question of capital, the company said they had £13,000 of the old capital applicable to electrical lighting; the maximum expenditure of £16,000 would be sufficient to supply the whole of this area; but if within the next twelve months there were applications to light a third of the area, it would be a very fair demand. Therefore the capital was more than sufficient to meet any immediate call; and if in three or four years' time they wanted more capital, he was sure the Board of Trade would give them permission to apply some of their new capital for the purpose. All the Gas Company asked was to be allowed, in open competition with anyone else, to supply electric light in a portion of the city. Some of the most eminent business men in the city had been examined, and had proved that in their opinion it would be in the interests of the citizens that this application should be granted. On the other there were only members of the Corporation and their *employés* examined; and it should be remembered that the Corporation were not elected on the question of electric lighting. He respectfully submitted that, under these circumstances, the Gas Company, he would not say were entitled, but they asked the Inspector for a favourable report, and asked the Board of Trade for the license they sought.

The Inquiry then terminated.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

"THE ELECTRICAL WORLD" IN THE UNITED KINGDOM

Arrangements have been made by which "THE ELECTRICAL WORLD" OF NEW YORK *can be obtained from* "THE ELECTRICIAN" *Office, 1, Salisbury-court, Fleet-street, London, E.C.*

The Rate of Subscription (payable in advance), is **£1 1s. 0d.** *per annum.*

Single Copies of "THE ELECTRICAL WORLD" *can also be obtained,* **price 6d. each.**

"THE ELECTRICIAN" *can also be obtained of the* W. J. JOHNSTON COMPANY (LIMITED), "THE ELECTRICAL WORLD" *Office, Potter Building, New York, U.S.A.*

LOCAL GOVERNMENT AND THE ELECTRIC LIGHT.

Some rather important extension of communal principles may naturally be expected from the popular character and powers conferred on the newly-created County Councils under the Local Government Act. An indication of this has already been given in the extreme self-assertiveness of the London representative body, notably in regard to the administration of the Electric Lighting Act, which the Council is evidently prepared to take on its own shoulders forthwith. Provincial Councils will not be backward in this respect we may be sure; and, their example reacting on the large towns and cities, a general desire is manifesting itself among local authorities to be doing something to justify their existence. The first thing that occurs to them to do is to set up business on their own account as suppliers of Gas and Water. Next in order will come the more ambitious aim of providing the Electric Light, an aspiration which has already found expression in the opposition of certain local vestries to the granting of Provisional Orders to outsiders, on the ground that if anybody is to have exclusive rights in this department of industry they ought to be vested in the local authorities. Only one English Corporation has as yet commenced the experiment, and that on a

Digitized by Google

limited scale, with not very encouraging results so far; but the rest are living in hopes that by delaying the applications of independent companies, sufficient knowledge of it may be gained to justify the business being started with capital borrowed on the security of local rates.

A curious illustration of this anxiety to extend their functions on the part of local corporations comes ready to hand from the City of Dublin, where an application on the part of the Gas Company to lay down underground wires for electric lighting purposes is opposed, partly no doubt because of misgivings as to the *bona fides* of the company, but chiefly because the Corporation itself wishes to retain the supply in its own hands, as it has already the supply of water. The evidence given before Major MARINDIN by the LORD MAYOR and members of the Dublin Corporation went to show that the management of the water supply is as pure as the water itself, and that altogether the chief city of Ireland is a perfect model of incorruptibility and public spirit. We are extremely glad to hear it, especially as reports of an opposite character have often reached us on this side of the Channel. But be that as it may, something more than good intentions is needed for the efficient management of electric lighting business; and, other things being equal, we should say that the Gas Company is more likely to command the required technical knowledge than is the Dublin or any other popularly elected municipal body. Not only this, a private company which is working for profit is more likely to conduct its business on economical lines than is a Local Authority with unlimited powers of borrowing and virtual irresponsibility as regards its expenditure. The shareholders of the Dublin Gas Company would constitute a very practical check upon extravagance or incompetence in the management of its affairs; the ratepayers of Dublin, as experience tells us everywhere else, are no check whatever on the doings of their representatives. Charges for a commodity supplied by the local authorities afford no criterion of the actual cost to the community, as the nominal price may be very low while the taxes to maintain it at that figure may be very heavy. In the case of Dublin, where the city authorities propose, like the Gas Company, to supply electricity to a limited area, the whole city would be taxed with the cost of the installation, and with any loss on the transaction if it failed, as probably it would, to be remunerative.

As, however, the dispute upon which Major MARINDIN has just been called to adjudicate in Dublin is complicated by the alleged shortcomings of the Gas Company, and its sinister motives in wishing to appropriate one of the best areas to the exclusion of a dangerous rival to the Gas interests, we are not prepared to offer any decisive opinion as to what the Inspector's verdict ought to be. Probably the Gas Company may be permitted to work under a Provisional Order if it chooses to apply for one. At present it claims to have the right to take up the streets and to supply electricity as "an improved method of lighting" under its original charter as a Gas Company. It will be interesting to note how this point will be decided; for, doubtless, the Dublin Company is not the only Gas Company that has a similar clause in its Act of corporation; and if their claims are upheld, many of the companies would be thus enabled to supply the electric light outside the provisions of the Electric Lighting Amendment Act, and consequently not subject to the purchase clauses incorporated in that or the Act of 1883. All that they would have to do would be to satisfy the Board of Trade that their scheme of supply was in accordance with regulations, and their system of wiring free from any danger to the public. We cannot believe that the Act of 1888 contemplated any such avoidance of its provisions; although, on the other hand, we should welcome any *bonâ fide* desire on the part of the Gas Companies to turn their attention to the business of electric lighting.

On the general questions of municipal socialism we may, perhaps, be content to let things take their natural course, circumstances varying in various localities, and what would be reckless speculation in one place might be judicious enterprise in another. For the present the local authorities as a rule will probably be well-advised in leaving the extremely technical business of electric lighting to professional experts, confining their trading instincts to the supplying of absolute necessities such as gas and water. If the subject of communal trading ever becomes the burning question here it threatens to be ere long in America, the sale of electricity will probably be excluded from consideration as a luxury not to be compared in importance with railroads, postal service, telegraphs, gas-light, and water. In the United States the acquisition by the State or by the local authorities of all these classes of undertakings, plus the electric lighting, is now being discussed very warmly, and is likely to become a serious political agitation. We say political, for although political ideas are disclaimed, it is notorious that matters of this sort cannot long be kept out of the political arena. "Spoils to the victors" is an established maxim of political warfare in America; and those who conscientiously oppose the tendency to Communism in that country declare it as one of their strongest objections that everybody will be compelled to become a politician, whether he likes it or not, if only to prevent the wholesale plunder which is one of the recognised rewards of political triumph, and which would be greatly enlarged if the supply of every necessity of life were to fall into the hands of the municipalities. We confess to some such apprehensions in regard to our own local affairs, which even now are sufficiently disturbed by the political strife of the times; and we think, therefore, that the ratepayers should keep a very close watch on any project whatever for extending the system rashly beyond its present limits.

ELECTRIC MOTOR REGULATION.*

BY FRANCIS B. CROCKER.

Although this subject is one of great scientific and practical interest, it has not been very frequently or very fully treated up to the present time. Of course, motor regulation is very similar to dynamo regulation, but it is by no means identical with it, and it deserves and requires separate treatment. I do not think it is much exaggeration to say that at the present time there is no subject more generally important to electrical engineers than motor regulation. Considering this fact, it is certainly remarkable that the literature of the subject is so limited. We find stray articles in electrical periodicals, rarely more than a description of one particular invention, and in electrical books, regulation is referred to incidentally in connection with descriptions of the various motors. There is also, to be sure, usually one short chapter devoted to this subject, but it is apt to be either very general, merely mentioning a few regulating devices, or else it is confined to the mathematical analysis of some one particular method.

Motor regulation is a subject which is somewhat confusing, and requires, therefore, accurate definition of the quantities and conditions which enter into it. One case is, at first sight, very similar to another, and yet more careful consideration will show, very likely, that it is exactly opposite. Take, for example, the two commonest and most important cases, viz., the constant-potential and the constant-current motors. The conditions of the two cases are precisely opposite, and the solution of the problem is, naturally, entirely different. To maintain a motor at a constant speed with a variable load, on a constant potential circuit, which is the case of the ordinary shunt motor on the regular 110-volt incandescent circuit, is a very easy problem—in fact, it solves itself. A simple shunt-wound motor will run at a practically constant speed on a constant potential circuit, even if the load varies from zero up to the full capacity of the motor. Now this form of motor is exactly

* A Paper read before the American Institute of Electrical Engineers, New York, May 22, 1889.

Digitized by Google

what we would use, even if we did not care to have it regulate. It is customary, to be sure, where very close regulation is required, to wind constant potential motors differentially, *i.e.*, with series as well as shunt coils, but this is not essential for ordinary work.

The case of the constant-current motor, on the other hand, is as difficult as the first is easy. It seems as if it had to bear the burden of both. Neither a shunt-wound, nor a series-wound, nor a compound-wound motor can be used practically on a constant-current circuit to maintain a constant speed with variable load. The ordinary series-wound motor, which is the natural and common form for the constant-current motor, will race away when the load is taken off and increase in speed until it tears apart or strains the armature and ruins the machine. We require some special and very effective device to accomplish the regulation in this constant-current case, and it seems to happen that almost every device that has been thought of has serious difficulties and complications. The ordinary, and what would seem to be the best, solution of this problem is to vary the magnetic effect of the field upon the armature directly in proportion to variations in the load. This is effected by cutting out the field coils, and by other methods which will be described later. But there are difficulties with almost all these plans.

These two cases, which, as already stated, are the commonest and most important which occur, and yet which are so very different in almost every respect, give a general idea of what we have to deal with in motor regulation.

In order to fix and hold the rather numerous quantities and conditions that present themselves in connection with motor regulation a tabular statement of them is given below :—

TABLE I.—Principal Methods of Motor Regulation.

1. Shunt winding. (*See* Fig. 1).
2. Differential winding. (*See* Fig. 2).

Varying external resistance in series with—

3. Armature.
4. Field. (*See* Fig. 1).
5. Both armature and field.

Varying internal resistance of—

6. Armature.
7. Field by cutting out coils in series. (*See* Fig. 3).
8. Field by cutting out coils in multiple arc. (*See* Fig. 4).
9. Field by grouping coils in series or multiple arc.
10. Both armature and field. (*See* Fig. 5).

Varying shunt in multiple arc with—

11. Armature.
12. Field.
13. Both armature and field. (*See* Fig. 6).
14. Varying current in separately excited field.
15. Shunting field magnetism. (*See* Fig. 7).
16. Short-circuiting field magnetism. (*See* Fig. 8).

Varying commutation by—

17. Shifting brushes. (*See* Fig. 9).
18. Shifting commutator.
19. Shifting magnetic resultant.
20. Moving pole pieces away from armature. (*See* Fig. 10).
21. Moving armature away from pole pieces. (*See* Fig. 11).

In Table I. motor regulation is divided into hand regulation, which it happens is almost always used for varying the speed of a motor, by a hand switch (Fig. 1 for example), and automatic regulation, which is almost always used to maintain a constant speed, and which is usually accomplished in one of the three following ways :—First, by a centrifugal governor similar to that of the steam engine, operating a switch or other device, Fig. 3 ; secondly, by a dynamometric governor, *i.e.*, a mechanism through which the load or torque of the motor is transmitted, which may also operate a switch and vary the power of the field by the direct effect of changes in the load ; thirdly, by an electro-magnetic device, such as a solenoid, through which the current, or a portion of it, is passed, which causes the core of the solenoid to move and operate a switch in accordance with variations in the current, Fig. 9.

The table gives the principal methods used to regulate motors. These consist of different arrangements and combinations of parts to produce different effects or changes in the working of the motor, and they constitute the means which we have to employ to accomplish a certain object in motor regulation. Method 1 is simple shunt-winding, which consists in exciting the field-magnet with a circuit of comparatively high resistance in multiple arc with the armature (Fig. 1). This maintains a motor at constant speed with varying load on a constant potential circuit, and does this all by itself, as it were, without any trouble, as already pointed out. The reason for this is that the field, being fed with a constant potential, is therefore of constant strength, and a slight variation in speed of the armature, about 5 per cent., will vary the current in it from zero up to its full capacity, and therefore vary its power to an equal extent.

Method 2 is differential winding (Fig. 2), which is a refinement of the first, by which an almost absolutely constant speed, *i.e.*, within 1 or 2 per cent., may be practically maintained. This consists in winding a series coil of comparatively few turns upon the field magnets, in addition to the shunt-winding in the previous case, the series coil being wound in the opposite direction and opposed magnetically to the shunt coil. The effect of this is to slightly weaken the field magnetism as the load on the armature, and consequently its current increases. This tends to increase the speed of the armature and counteract its tendency to slow down with increased load, thereby almost entirely eliminating even the small variation of 5 per cent. in speed which occurs in the ordinary shunt motor. The paradoxical fact that a shunt motor increases its speed with the weakening of the field-magnet is well known, being due to the lowering of the counter electromotive force and consequent increase of current in the armature as the field magnetism is reduced in intensity.

In the next three methods the external resistance in series with the armature or field, or both, is varied. Method 3 would be very wasteful, and is hardly allowable in good practice, because it is simply destroying the main current to put resistance in the armature circuit. Method 4, varying the resistance in the field circuit, is very much less objectionable, and is very convenient and common (Fig. 3). This mode can be adopted with a very small loss of current, because the field current is only a small part of the total current used in the motor, and the loss of a portion of this small fraction is practically insignificant. Method 5, putting external resistance in series with both the armature and field, is open to same objection as Case 3, since it throttles and destroys part of the main current.

The next five modes of regulation, 6, 7, 8, 9 and 10, are theoretically more economical than the preceding, because we vary the internal or useful resistance instead of adding external or dead resistance. Method 6, in which the internal resistance of the armature is varied, is very difficult to carry out in practice, simply because it is hard to get at and change the connections of the armature while it is revolving. One of the few ways devised to accomplish this is to wind the armature with two or more circuits connected to a corresponding number of commutators, whereby one or more of these circuits may be used, thus varying the internal resistance and torque. This is clumsy, and practically little better than using two or more separate motors.

Method 7, cutting out the field coils in series, is a very simple and common plan. It is the ordinary way of regulating constant-current or other series-wound motors. This method, or some modification of it, is one according to which the constant-current or "arc" motors of the Baxter, "C. and C." and Excelsior companies are constructed. Method 8, of cutting out field coils in multiple arc, is shown in Fig. 4, and is especially applicable to shunt-wound motors. The different layers, for example, may be respectively connected to the contact points of a switch and thrown into circuit successively, the innermost layer first, &c., thus obtaining the most economical result.

Method 9, of grouping the field coils in series or multiple arc, produces very great variations in field resistance and is a combination of the two preceding cases. Like them, it consists in winding the field with separate circuits which are connected to a switch. This is employed in street-car motors to obtain the great variations in resistance and power required of them.

Method 10 is also merely a combination of two or more of the four preceding cases. A simple way of carrying it out is illustrated in Fig. 5, and consists in connecting the armature and field either in series or in multiple arc, by which a great variation in the total internal resistance of the machine is obtained.

The next method, No. 11, is open to the same objection as No. 6, because when the armature is shunted the main current of the machine is affected. This is, however, less objectionable than dead resistance, because in most cases it is better to divert the current than to destroy it.

Method 12, like methods 4 and 7, is a useful and common one, because in shunting the field we are merely handling a very small fraction of the total current.

Method 13, varying a shunt in multiple arc with both armature and field, is wasteful, like No. 11. It was, however, the plan by which the first arc motors were regulated, a variable shunt being placed in the main circuit and the motor connected to the terminals of the shunt.

The variations in the shunt, of course, throw more or less current through the motor, thereby varying its power as required.

Method 14, varying the current in a separately excited field, is merely historical, as this class of motors has gone out of use. The plan, however, is a very effective one, because, of course, it is very easy to control the field current when it is produced by a separate source.

Method 15 is shown in Fig. 7, and consists in shunting the field magnetism, *i.e.*, diverting the lines of force from the armature through some other path. In the arrangement shown in Fig. 7,

Digitized by Google

there is a simple series-wound motor with consequent pole field magnet, and, if the coils exciting one magnetic circuit are short-circuited, it is evident that the magnetism produced in the other magnetic circuit will be short-circuited or shunted by the former.

We now come to methods 17, 18, and 19, in which the line of commutation is varied. The first is the well-known plan of shifting the brushes. This is very effective and easily carried out, and has, therefore, been used quite extensively, but it has the very serious and almost prohibitory objection that when the brushes are moved from the neutral point they spark very badly. This may be remedied to a slight extent by some heroic plan like blowing out the spark produced. But, as sparking is one of the worst drawbacks of a motor, it hardly seems as if this method of regulation would be permanent.

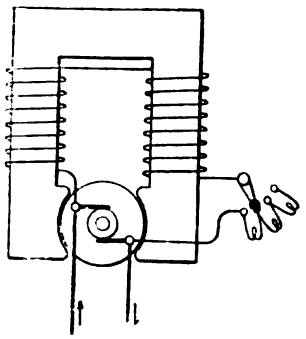

FIG. 1.—Shunt Motor, with Variable Resistance in Field Circuit.

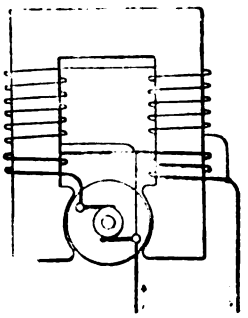

FIG. 2.—Differential Motor. Self-Regulating.

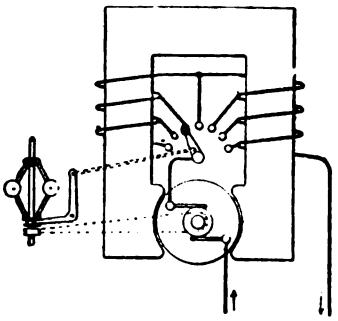

FIG. 3.—Series Motor with Switch for Cutting Out Coils in Series.

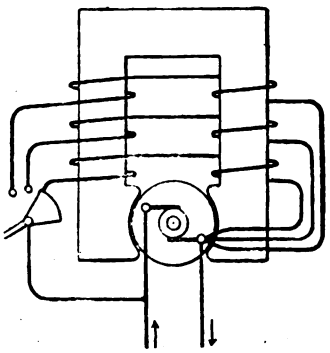

FIG. 4.—Shunt Motor with Switch for Cutting Out Field Coils in Multiple Arc.

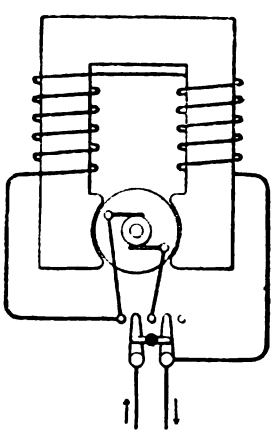

FIG. 5.—Motor with Switch for Throwing Armature and Field in Series or in Multiple Arc.

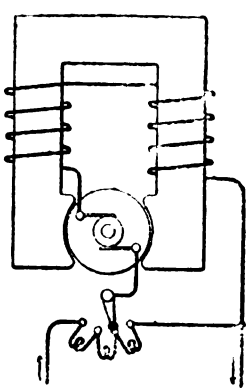

FIG. 6.—Series Motor on Variable Shunt.

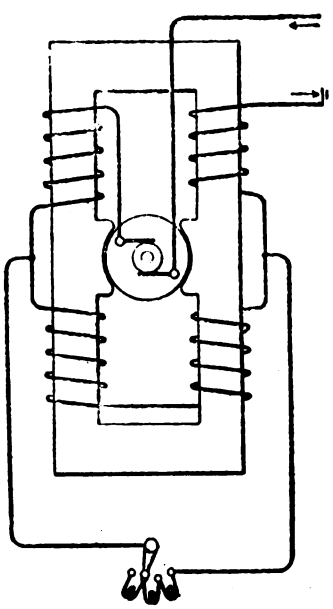

FIG. 7.—Series Motor with Variable Magnetic Shunt.

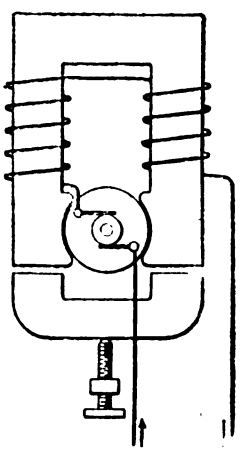

FIG. 8.—Series Motor with Variable Magnetic Short Circuit.

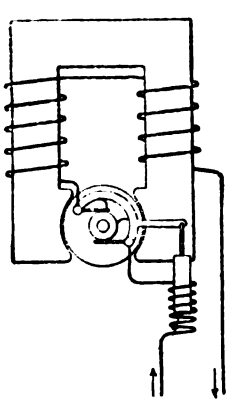

FIG. 9.—Series Motor with Automatic Device for Shifting Brushes.

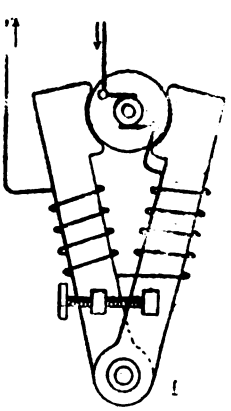

FIG. 10.—Series Motor with Device for Moving Pole Pieces Apart.

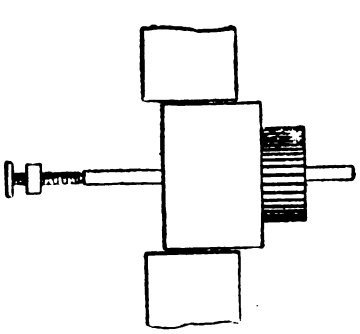

FIG. 11. - Series or Shunt Motor with Regulator for Moving Armature Out of Field.

The short-circuiting of the coils is effected by the variable shunt, as indicated.

Method 16 is very similar to the preceding, and consists in short-circuiting the field magnetism and diverting it from the armature by a keeper, which may be moved towards or away from the pole pieces by means of a screw or other contrivance.

Digitized by Google

Methods of regulation which are all right for dynamos may not be allowable in the case of motors, because the former are usually in the hands of skilled men devoted to their care, while motors are often run by ignorant and careless persons.

Method 18, shifting the commutator, is simply another way of doing the same thing as shifting the brushes.

Method 19, shifting the magnetic resultant or direction of lines of force in the armature, may be accomplished by two sets of pole pieces, the relative magnetic strength of which is varied. This is also open to the same objection as shifting the brushes.

Method 20, shown in Fig. 10, consisting in moving or separating the pole piece from the armature, has been used in the Diehl and other motors, but it is rather difficult to carry out mechanically, and introduces a hinge or joint in the magnetic circuit, which is, of course, very undesirable.

Method 21, moving the armature away from the pole pieces, is very much easier to accomplish mechanically, and has a great many advantages as a means of regulation. Mr. S. S. Wheeler and myself have been working for some time on motors in which this method of regulation is employed, and the results we have obtained been very satisfactory; in fact, we have found it to be extremely simple, effective, and reliable.

(To be continued.)

THE BOARD OF TRADE INQUIRY.

The following is the portion of Major Marindin's report which, for the sake of economising space, we previously omitted. It may be added that, so far as we are aware, this section has not hitherto been printed in any other journal. It will be found to contain a good summary of the leading features elicited during the Inquiry :—

The cases were for convenience taken in the following order :—

I. *The London Electric Supply Corporation*, represented by Mr. Pember, Q.C., Mr. Loyd, and Mr. Graham, instructed by Messrs. Deacon, Gibson and Medcalf.—This Company having struck out several of the parishes originally included in these Orders, now seeks for powers in the following areas :—The parishes of St. Martin-in-the-Fields ; St. Margaret and St. John, Westminster (except that portion of the parish of St. Margaret, Westminster, which lies to the west of St. George, Hanover-square) ; St. James's, Westminster ; St. George, Hanover-square ; Chelsea ; part of the parish of St. Marylebone ; part of the parish of St. Pancras ; St. James and St. John (united), Clerkenwell ; the Strand District, the St. Giles District, the Holborn District, the City of London and the Libraries thereof, and the extra-parochial places of Lincoln's Inn, Gray's Inn, and the Inner and Middle Temple, all in the county of Middlesex ; the Greenwich District, in the county of Kent ; the parishes of St. Mary, Rotherhithe, and St. Mary, Bermondsey ; part of the parish of St. Mary, Lambeth ; the district of St. Olave, and the district of St. Saviour's and Christchurch, all in the county of Kent.

The following local authorities only in the above area have given their assent, viz. :—St. George (Hanover-square) Vestry, Chelsea Vestry, St. James and St. John (Clerkenwell) Vestry, St. Giles District Board, Holborn District Board.

The attitude of the remaining local authorities is as follows :—

St. Martin-in-the-Fields Vestry, Greenwich District Board, Rotherhithe Vestry, Bermondsey Vestry, St. Olave District Board, have passed resolutions of assent, subject to the insertion of certain amendments in the Order.

The City (the Commissioners of Sewers), the Strand District Board, St. Margaret and St. John (Westminster) Vestry, St. Marylebone Vestry. St. Pancras Vestry, dissent and oppose.

St. James (Westminster) Vestry, St. Mary (Lambeth) Vestry, dissent, but on terms would assent.

St. Saviour's District Board, which had assented conditionally, has withdrawn assent, but did not appear at the Inquiry to oppose.

The St. James and Pall Mall Electric Light Company, a company holding a License in the parish of St. James, is also competing and objecting to the Order of the London Corporation.

The London County Council took no part in the proceedings, but two members of the Board, Mr. A. H. Haggis and Mr. T. W. Benn, and the engineer, Mr. T. Percy Gunzon, attended on behalf of the Council.

System of Supply.

The London Electric Supply Corporation, although, as in the case of all the other companies, no particular system is specified in the Order, proposes to supply, by means of high-pressure alternating currents and transformers, with one generating station only, at Deptford, transforming or distributing stations in the different parts of the district, and transformers in the customers' houses.

The pressure in the trunk mains from Deptford will be 10,000 volts, and in the distributing mains 2,400 volts, which will be again transformed into 100 or 50 volts inside the consumers' premises.

Capital.

The capital of the Corporation is £1,250,000, the subscribed capital is £805,000 in £5 shares, and the paid up capital is £586,300, of which about £430,000 has been expended, or is committed by contracts.

The Order, as amended, contains no provision for any allocation of capital or deposit, and no clauses, except for the parish of Chelsea, requiring a compulsory laying of mains in any area (A.) or any scheduled streets, but mains are to be laid in any part of the area on requisition after a lapse of 18 months.

Price.

For purposes of charging consumers, the new unit, which is ten times as great as the present Board of Trade unit is proposed, the maximum price being "for any quantity up to 15 units £5, and for each unit over 15 units 6s. 8d. per unit," which is equal to 8d. per Board of Trade unit.

I do not here propose to deal with all the clauses of the Order, which, however, varies in many respects from what has been considered the model Order, but there are two clauses (Nos. 55 and 36) which are of a novel character.

No. 55 empowers the Corporation to supply electricity in bulk to any local authority who may under the terms of the Order borrow money on the security of the rates for this purpose, and exercise generally in their district all the powers conferred upon the undertakers, or contract with the undertakers.

No. 56 exempts the company from the strict application of the rules as to dimensions of buildings in the Metropolitan Building Act, 1855, and is intended to cover a departure from this rule in the case of their generating station at Deptford.

Objections.

The objections to the Order by local authorities are fully set forth in the record of the proceedings, and in the documents which have been lodged with the Board of Trade ; but they may be generally stated to be the experimental character of the scheme, the size of the area applied for, the insufficiency of capital, the absence of clauses providing for allocation of capital, deposit, compulsory area of supply, the safety of the public, and the removal of overhead wires, the want of proper provision for the protection of local authorities in the matter of the breaking up of streets, and the unsatisfactory nature of the clauses as to supply, and the interference with drains and the pipes of gas, water, and other companies.

The City authorities object to any company having statutory powers to break up the streets, and contend that they have power to contract for a supply.

The Strand and St. Marylebone authorities object to more than one company having powers in their districts, and to the form of the London Order and the nature of the scheme, and have entered into agreements with the Metropolitan Company.

St. Margaret and St. John (Westminster) Vestry objects to the entrance of any company in the present state of electrical science, and in the absence of any special demand for electricity.

St. Pancras Vestry, which obtained a Provisional Order in 1883, but has not acted upon it, objects because it is probable that the duty of lighting will now be undertaken by the Vestry.

It seems probable that the objections of the other local authorities can be met by the insertion of clauses.

The competing companies using the rival systems, and to some extent the Metropolitan Company, attack that of the London Company upon various grounds, which will be dealt with further on, and while the Metropolitan Company does not object to competition, the other companies urge that it is unnecessary and objectionable.

II. *The Metropolitan Electric Supply Company.*—This company having withdrawn their North London Order, now seeks for powers under three Provisional Orders and a Bill, with the following areas, viz. :—

The Mid-London Order, including the following parishes and places in the Metropolis and the County of Middlesex, viz. :—The City of London and the Liberties thereof ; and the following parishes and places in the County of Middlesex, viz. :—St. John the Evangelist, Westminster ; St. Margaret, Westminster ; St. George, Hanover-square ; St. Giles-in-the-Fields ; St. George, Bloomsbury ; St. Andrews, Holborn above Bars ; St. George the Martyr ; St. Sepulchre, Saffron-hill ; Hatton-garden ; Ely-rents and Ely-place ; the Liberty of Glasshouse-yard ; St. Anne, Soho ; St. Paul, Covent-garden ; St. John the Baptist ; Savoy, or precinct of Savoy ; St. Mary-le-Strand, St. Clement Danes, and the Liberty of the Rolls, together with the extra parochial places known as the Charter House, Gray's Inn, Lincoln's Inn, Staple Inn, Furnival's Inn, and the Close of the Collegiate Church of St. Peter.

The South London Order, including the following parishes and places in the Metropolis and in the county of Surrey, viz., St. Mary, Lambeth, Christchurch, St. Saviour's (including the Liberty of the Clink), St. Leonard's, Streatham, and Clapham.

The West London Order (as amended), including the following parishes in the Metropolis and in the county of Middlesex, viz., St. Marylebone and Paddington.

The Bill, including the parishes of St. James, Westminster, and part of St. Martin-in-the-Fields, in the county of Middlesex ; Waterloo Bridge, partly in the county of Middlesex, and partly in the county of Surrey, and the approaches thereto ; and so much of the Victoria Embankment as lies between Waterloo Bridge and the boundary of the parish of St. Martin-in-the-Fields.

The following local authorities in the above areas have signified their assent, viz. :—

In Mid-London : St. George's, Hanover-square, Vestry ; St. Giles District Board for St. Giles-in-the-Fields and St. George, Bloomsbury ; Holborn District Board for St. Andrews, St. George the Martyr, St. Sepulchre, Saffron-hill, Hatton-garden, Ely-rents, and Ely-place, and the Liberty of Glasshouse-yard ; Strand District Board for St. Anne, Soho ; St. Paul, Covent-garden, St. John the Baptist, Savoy, St. Mary-le-Strand, St. Clement Danes, Liberty of the Rolls. (Subject to special agreement).

Digitized by Google

In South London: Nil.

In West London: St. Marylebone Vestry. (Subject to special agreement).

To the Bill: St. James, Westminster, Vestry; St. Martin-in-the-Fields Vestry.

The attitude of the remaining local authorities is as follows:—*In Mid-London:* The City; St. Margaret and St. John, Westminster. Dissent and oppose.

In South London: Lambeth Vestry; Wandsworth District Board for the parishes of Streatham and Clapham. Have withheld consent, but do not actively oppose, and would consent on terms.

St. Saviour's District Board for St. Saviour's and Christchurch, which had assented conditionally has withdrawn assent, but did not appear at the inquiry to oppose.

In West London: Paddington Vestry dissents and opposes.

The other competing electric lighting companies applying for powers (also represented as above) were:—

In Mid-London: The London, the Kensington Court, the Westminster, the Chelsea, and the Electrical Power Storage.

In South London: The London.

In West London: The London; the Electrical Power Storage.

In the Area under the Bill: The London; the Electrical Power Storage.

In this area the St. James and Pall Mall Electric Light Company, at present supplying under a License, is an objecting company.

There are other objectors to the Orders asking for insertion of clauses for their protection, as in the case of the London Order.

System of Supply.

The system proposed to be adopted by the Metropolitan Company, except at the existing station at Whitehall-place, is, as in the case of the London Company, that of high-pressure alternating currents and transformers, but it differs from the London system in details which will be referred to more particularly hereafter. It necessitates several generating stations instead of one, the sites at present selected being situated in Sardinia-street, Rathbone-place, South-mews, near Manchester-square, Eccleston-place, and Waterloo Bridge Wharf. The pressure in the mains will be 1,000 volts, which will be transformed into 100 or 50 volts inside the consumers' premises.

At Whitehall-place the direct-current system with storage batteries, now in use, will be maintained.

Capital.

The capital of the company is £500,000 in £10 shares, of which £43?,0?0 is subscribed, and £3 per share, or £131,900 in all, is paid up. There are 700 shareholders, and the company has spent, or is under obligations to spend, a sum of £351,?00.

The Orders, except as varied by the Strand and Marylebone Agreements, contain no provision for any allocation of capital or deposit, and no clauses requiring a compulsory laying of mains in any area (A) or any scheduled streets, but there is an obligation to lay mains in any part of the area on requisition after a lapse of 18 months.

In the Strand and Marylebone agreements streets have been marked upon a scaled map, in which the mains shall be laid down and completed within eighteen months after the granting of the Order.

Price.

The Metropolitan Company also proposes to adopt the new unit in place of the Board of Trade unit, and the maximum price in their Orders was "for any quantity up to 15 units £5. 10s.; for each unit over 15 units, 6s. 8d. per unit."

This price has been maintained in their South London Order, but a different scale having been agreed to for Strand District and Marylebone, the same price necessarily became that for both the Mid-London and West London Orders. It is as follows: "For any quantity up to two units 13s. 4d., and for each unit over two units 6s. 8d. per unit."

The rate per unit is not altered, and is equal to 8d. the Board of Trade unit.

In the Bill the Board of Trade unit has been adhered to, and the price is "for any quantity up to 100 units, £3. 10s.; and for each unit over 100 units, 7d. per unit."

The Orders differ in many respects from the Model Order, but contains no clauses which at this point require special mention.

The Strand and Marylebone Agreements.

The agreements entered into by this Company with the Strand and Marylebone local authorities contain provisions of an unusual character, which should be carefully considered in connection with the objections and suggestions as to clauses lodged by other local authorities before they are embodied in the Orders.

Clause 70*b*, which it is proposed to insert in the Order, stipulates that if there be any provisions in the Agreements inconsistent with those in the Order the provisions of the Agreements shall prevail.

Objections.

Paddington Vestry opposes the West London Order, because a scheme for the lighting of the parish by the Vestry is under consideration, and likely to be adopted.

Wandsworth District Board does not oppose the South London Order in principle, but asks for the insertion of clauses, the scheduling of streets in which the mains must be laid within 18 months, a reduction of price to 7d. per unit, the insertion of a provision for a sliding scale, and the incorporation into the Order of Sections 109, 110, and 111 of the Metropolis Management Act of 1855.

The objections of the City, and of other local authorities withholding consent, are of a similar character to those lodged in the case of the London Company, with the exception of the objection to the experimental nature of the scheme. These objections, other than those of the City and St. Margaret and St. John, Westminster, can probably be met by the insertion of clauses considered satisfactory by the Board of Trade.

The competing companies attack the system proposed for adoption, but not so strongly as in the case of the London Company.

The London Company does not object to the competition of the Metropolitan, and does not attack the system, but considers its own system the better of the two, inasmuch as it provides for all the manufacture of electricity being carried on outside the crowded part of the Metropolis.

III. *The House-to-House Company.*—This company applies for powers over the whole parish of St. Mary Abbotts, Kensington, with the exception of certain streets (specified in Schedule A of the Order) lying to the east of Kensington High-street Station, but it is willing to accept a district allotted by the Kensington Vestry, being the south-western portion of the parish.

The only local authority concerned is the Vestry of Kensington.

This Vestry has districted the parish among all the companies seeking for entrance, six in number, allotting certain portions to each as an Area A, and considering the remainder as an Area B, which the Vestry may call upon any of the other companies to take up.

The London and Metropolitan Companies having refused to enter on these terms, the Vestry is considering how best to deal with the two abandoned portions, those at the northern extremity of the parish.

The Vestry asks for the insertion of clauses, but will accept whatever the Board of Trade may consider reasonable.

The House-to-House Company has signified its assent to some of these clauses, and will abide by the decision of the Board of Trade, so that, as far as the Local Authority is concerned, this may be considered an agreed Order.

The other companies now promoting Orders in this parish are –

The Chelsea Company on the south-east side.

The Notting Hill Company in the west-central part of the parish.

The Kensington Court, or Kensington and Knightsbridge Company, in the east-central part.

These companies oppose *pro formâ*, and criticise the system of the House-to-House Company but only the last named asks for a revision of the area. wishing to annex two pieces out of the portion allotted to the House-to House Company.

This does not seem reasonable, except, perhaps, as regards one very small piece in Kensington High-street, in which the Kensington Court Company has laid mains.

The question should, I submit, be left for the decision of the local authorities, who seem to have gone very carefully into the matter.

System of Supply.

The House-to-House Company proposes to supply by means of the high-pressure alternating currents and transformer system, with one or more generating stations, as may be required, a pressure in the mains of 2,000 volts, and transformers in the customers' houses, where the pressure will be 50 or 100 volts.

There is a generating station now at work near West Brompton Station, at the south-west corner of the parish.

Capital.

The capital of the company is £350,000 in £5 shares, of which the sum of £41,600 is subscribed.

The Order contains no provision for any allocation of capital or deposit, and no clause rendering it compulsory to lay mains in any scheduled streets. There are the usual requisition clauses, but the period to elapse before the undertakers can be called upon to lay mains, viz., three years, is too long, and should be reduced.

Price.

This company also proposes the new unit in Schedule B relating to price, and proposes to charge under two scales.

Plan A, on the basis of a sliding scale at the rate of 10s. per unit for the first 100 units, 6s. 8d. per unit for the second 100 units, and 3s. 4d. per unit for any further quantity. These prices are equivalent to 1s. 8d. and 4d. per Board of Trade unit.

Plan B.—For any quantity up to 15 units, £5, and for every unit over 15 units, at the rate of 6s. 8d. per unit.

There is also the usual section as to charge per hours, and a section of a more novel character providing for the fixing of a standard price and sliding scale on the basis of a 10 per cent. dividend after the expiration of seven years.

It does not appear probable that the method of charging under Plan A would be an advantage to the general consumer, and the local authority objects to it.

IV. *The Notting Hill Company.*—This company schedules as the area of supply the whole parish of St. Mary Abbott, Kensington, in the county of Middlesex, although the original application to the Vestry was only for a portion of the parish, the remainder of the parish being included in accordance with the request of the Vestry.

The company accepts the portion allotted by the Vestry as the area A.

The attitude of the Vestry is similar to that taken in the case of the House-to-House Company, and the Order may be considered as an agreed Order. The objections lodged by other companies are not pressed.

The proposed method of supply is that used by the Kensington Court Company, viz., the direct supply by means of continuous currents, partly from accumulators and partly from batteries.

Digitized by Google

No works have been erected, or, so far as the evidence goes, designed. The nominal capital of the company is £100,000, but nothing beyond the sum necessary for preliminary expenses has been subscribed.

There are no clauses in the Order providing for allocation of capital, deposit, or compulsory laying of mains, but the works necessary for supply are to be commenced within a period of four months after the commencement of the Order.

This company proposes the new unit, and proposes to charge "For any quantity up to 10 units £3. 6s. 8d., and for each unit over 10 units at the rate of 6s. 8d. per unit." This charge is equivalent to 8d. per Board of Trade unit.

Provision is also made for the fixing of a standard and sliding scale on the basis of a 12 per cent. dividend after the lapse of seven years.

V. *The Kensington and Knightsbridge Company.*—This company applies for powers over the whole parish of St. Mary Abbotts, Kensington, and so much of the parish of St. Margaret, Westminster, as lies to the west of the parish of St. George, Hanover-square.

The following are the only local authorities concerned :—

The Kensington Vestry.

The Vestry of St. Margaret and St. John.

The former Vestry has dealt with this company, which is already supplying in the parish under Licenses in the name of the Kensington Court Company, precisely as they have with the other competing companies in the parish, and the Order, so far as the allotted area in this parish is concerned, may be taken as agreed, subject to the decision of the Board of Trade in the matters of certain alterations and clauses asked for by the Vestry.

The latter Vestry dissents, and objects to the period agreed to in two Licenses, under which the company is supplying the whole of the residential area of this outlying part of the parish, being extended by a Provisional Order to 42 years.

The Notting Hill and Chelsea Companies, who are also in Kensington, do no more than oppose formally ; the House-to-House strongly opposes any invasion of the area allotted to it by the Vestry, as is proposed by the Kensington and Knightsbridge Company ; and the Metropolitan Company is competing for the whole of the portion of St. Margaret's parish included in this Order.

The system adopted by this company, and now in work at the Kensington Court Station, is the direct supply by means of continuous currents, partly from accumulators and partly from dynamos.

There is a second generating station in Chapel-street at the east end of the area, which is nearly ready for the commencement of working, and these two stations will be sufficient for the whole area.

The capital of the company is £200,000 in £5 shares, with about £38,000 paid up, and about £75,000 more promised to be subscribed.

The Order contains no clauses for allocation of capital, deposit, or compulsory laying of mains in any scheduled streets, but there is an obligation to supply under the usual terms on requisition at any time after the expiration of a period of three years.

In the schedule as to price the new unit is proposed, and the charge is as follows :—"For any quantity up to 15 units £5, and for each unit over 15 units 6s. 8d. per unit. This is equivalent to 8d. per Board of Trade unit.

VI. *The Chelsea Company.*—This company, which is supplying in the parish of Chelsea, under a Provisional Order confirmed by Parliament in 1886, is promoting two Orders, viz. :—

The South Kensington Order.

The Belgravia Order.

I. South Kensington Order.

As regards the first, the company is in a somewhat different position to the other companies in Kensington, the area allotted to it being a small portion of the parish of St. Mary Abbotts, at the east end of the parish contiguous to Chelsea, the whole of which is an Area A, with certain streets scheduled in which mains are to be laid within three years from the commencement of the Order.

This Order may be taken as an agreed Order, subject to the decision of the Board of Trade as to alterations proposed by the Vestry of Kensington.

The system proposed is the direct supply, by means of continuous currents, entirely from accumulators in several distributing stations, whence the current will be taken at a pressure of from 1,000 to 2,000 volts. In the supply mains from the distributing stations to the consumers' houses the pressure will be 100 volts.

The generating station is nearly completed, and is situated in Draycott-place, near Sloane-square.

The total capital of the company is £100,000, in £5 shares, of which £18,000 is to be appropriated for the purposes of this Order.

The total amount subscribed is about £33,000, of which about £25,300 has been expended or is contracted for. Out of the £33,000 an amount of £23,000 is subscribed by three manufacturing companies, who have contracts for carrying on the works of the company, viz., the Electrical Power Storage Company, the Anglo-American Brush Company, and Callender's Bitumen Telegraph and Waterproof Company.

It is proposed to increase the capital to £200,000, and the amount which will be expended when the full plant is at work is £108,000.

There is a clause providing for a deposit.

The provisions as to price are as follows, the Board of Trade unit being adhered to :—

"For any quantity up to 84 units, £3. 10s., and for each unit over 84 units, 8d. per unit."

II. Belgravia Order.

In the Belgravia Order the company seeks for powers over so much of the parish of St. George, Hanover-square, as is between the line formed by the eastern boundary of Chelsea parish on the west, by Knightsbridge, St. George's-place, and Hyde Park Corner on the north, and by Grosvenor-place, Upper Grosvenor-gardens, Lower Grosvenor-gardens, Buckingham Palace-road, Commercial-road, and Bridge-road on the east and south east.

There are scheduled streets within this area in which the undertakers are bound to lay distributing mains within three years. These streets comprise nearly all those in the area.

The only local authority is the Vestry of St. George, Hanover-square, which objects to the entry of the company, for the reason that permission has already been granted to three other companies, who agree to take the whole parish.

These companies, the London, the Metropolitan, and the Westminster, oppose the Order : the two first-named upon the grounds of the unsatisfactory financial position of the company, and not because they object to competition.

The capital proposed to be appropriated to the purposes of this Order is £30,000, and there is a clause providing for a deposit being made.

The system is the same as that in this company's South Kensington Order, and the provisions as to price are identical.

VII. *The Westminster Company.*—This company seeks for powers to supply in the following area, as amended, viz., part of the parish of St. Margaret and St. John the Evangelist (the outlying portion being omitted), and the Parish of St. George, Hanover-square.

The local authorities affected are the Vestries of St. George, Hanover-square, and of St. Margaret and St. John the Evangelist.

The former assents to the Order, and the latter dissents and opposes for the reason already given in the case of other companies.

The competing companies over the whole area are the London and the Metropolitan Companies, who do not object to the competition but to the financial position of the Company, and to some extent to the system of supply proposed for adoption. The Chelsea Company are a competing company in a part of the parish, and also oppose.

The system which it is proposed to adopt is that of the Kensington and Knightsbridge Company, viz., the direct supply by means of continuous currents, partly from batteries and partly from dynamos. There is a site at Victoria Mansions where the boilers and plant for 5,000 lights are nearly erected, but it is not proposed that this shall be a permanent station, and the scheme of the company does not appear to have been definitely settled.

The proposed capital is £100,000 in £5 shares, of which about £8,000 is subscribed privately.

There are only seven shareholders in the company, but subscriptions to a large amount are promised.

The Order does not contain clauses for the allocation of capital or deposit, and there is no compulsory area of supply.

The new unit for price is proposed, and charge is :—For any quantity up to 15 units, £5, and for each unit over 15 units, 6s. 8d. per unit.

VIII. *The Electrical Power Storage Company.*—This company is promoting two Orders, viz. :—

The Paddington Order ;

The St. Martin's and Strand Order.

I. The Paddington Order.

The first Order is for the whole of the parish of Paddington, divided into two areas, A and B, with scheduled streets in the former area in which mains must be laid within three years.

The only local authority, the Vestry of Paddington, opposes the Order because the supply by the Vestry itself is contemplated.

The only company competing for this parish is the Metropolitan Company, which company objects to the granting of the Order on account of the constitution of the company

The capital of the Electrical Power Storage Company is £200,000 in £5 shares, but of this sum nothing is appropriated for the purposes of this Order. The proposed capital for the undertaking is £60,000, none of which has been actually subscribed, although evidence was put in to the effect that certain large shareholders have agreed to find this sum, of which £30,000 is to be allocated to Paddington and £30,000 to St. Martin's and Strand.

No evidence was given as to the proposed system, but it would doubtless be similar to the Chelsea system.

No information was given as to the sites of proposed works, even if they have been selected.

The scale of prices is the same as that in the Chelsea Order, the old Board of Trade unit being adhered to.

In regard to the St. Martin's and Strand Order, the provisions are identical to those in the Paddington Order.

II.—The St. Martin's and Strand Order.

The local authorities are :—The Vestry of St. Martin's, which assents, and the Strand District Board of Works, which opposes, for the same reasons as are given in the case of the London Company.

The competing companies are the London and the Metropolitan Companies, both of whom strongly oppose the granting of the Order on the grounds that the Electrical Power Storage Company is seeking for powers which it is not in a position to carry out, but will have to dispose of to other parties.

London Fogs.—The Sanitary and General Purposes Committee of the London County Council have been instructed "to take into consideration the causes of the fogs which trouble London during the winter months, and the increased death rate during their prevalence, in order to put in force existing powers for dealing with them, and obtaining increased powers, if necessary."

Digitized by Google

THE PHYSICAL SOCIETY.

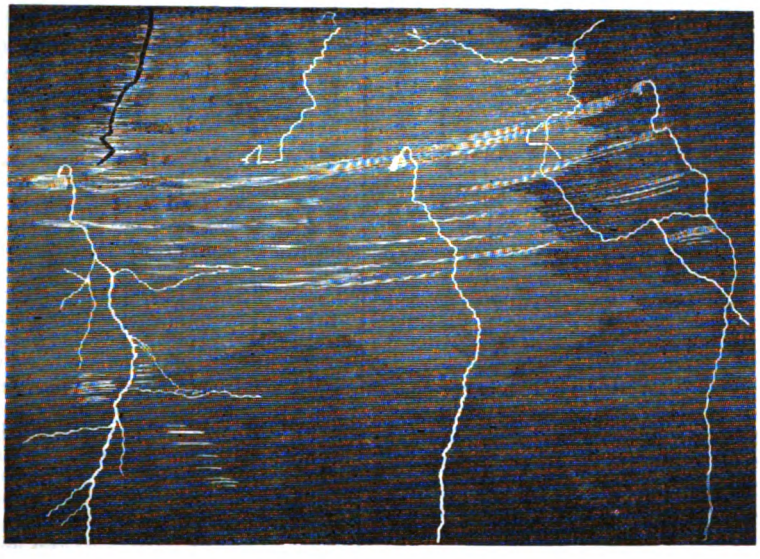
At the meeting of this Society on the 8th inst. Dr. HOFFERT exhibited

"A Photograph of a Lightning Flash"

which he had taken during the thunderstorm of the 5th inst. The photograph was taken while the camera was being waved backwards and forwards in the hands. It shows three similar parallel flashes, thus proving that successive discharges, separated by appreciable intervals of time, traversed the same path. The flash which Dr. Hoffert believes to be the primary one has numerous branches spreading out from it on each side, but the second flash has only one such branch, and the third flash has none. The space between the flashes is traversed by faint bands of light parallel to the direction of motion, appearing to indicate the existence of a residual illumination of a phosphorescent character in the intervals between the successive flashes. A dark flash crossed by similar bands of light is also shown on the negative; which disproves the explanation suggested by Mr. Whipple in a Paper recently read before the Society, viz., that the so-called dark flash was due to internal reflection in the glass negative during the process of printing.

DISCUSSION.

In the discussion which ensued Prof. A. S. HERSCHEL stated that he had taken some photographs of flashes during the same storm, and the points which he had specially remarked were the fluttering appearance of the flashes and their long duration, this being sufficient in many cases to enable him to direct the camera towards an observed flash, and obtain a photograph of it. He had not waved his camera in order to obtain evidence of multiplicity in the flashes, but in several cases he had been able by means of the naked eye to detect a series of flashes following the same path, and on moving his head from side to side he had counted as many as a dozen distinct images of what otherwise appeared to be a single discharge.



Photograph of a Lightning Flash taken with Moving Camera.

Mr. GREGORY said that he and two friends had watched the storm together, and they were scarcely ever able to agree about the shapes of the flashes or about the simple or multiplex character. He thought that the want of agreement as to the multiplicity might be due to their eyes being directed towards different parts of the sky when a multiple flash occurred, as the one who happened to be looking in the direction of the flash might only be conscious of one impression, while the others might, while turning their eyes towards it, receive several impressions on different parts of the retina. In some cases they had observed as many as three distinct flashes following the same path at intervals of about ten seconds. Many of the flashes presented a beaded or striated appearance, and the impression of the beads remained on the retina after that of the flash had faded away. This latter phenomenon might perhaps be due to the same cause as the bright bands in Dr. Hoffert's photograph.

Mr. C. V. BOYS commented on the hesitation which had been shown in accepting the statements which he had made with respect to multiple flashes during the discussion on Mr. Whipple's recent Paper, and he was convinced that no one who had watched the recent storm could continue to doubt their occurrence. He thought the best observations could be made at distances of from three to ten miles, as the observer could then see all the phenomena without the disturbance to his mental equilibrium which might arise from a dangerous proximity to the discharges.

Prof. S. P. THOMPSON thought the order of the flashes might have been the reverse of what Dr. Hoffert supposed, for the faint bands of light extended on both sides of the flash which he considered to be the primary one, whereas the outside edge of the third flash was quite dark.

Mr. E. W. SMITH stated that he had observed many cases of sympathetic discharge in which a flash in the north seemed to precipitate another in the north-west within a second or two.

Mr. C. V. BURTON thought the heating of the air by the primary flash might give rise to the branching of the succeeding ones.

Mr. A. W. WARD had been particularly impressed by the long duration of a flash which he had observed at Cambridge, and which appeared to come from the zenith, and then struck some farm buildings at a distance.

Prof. S. P. THOMPSON then read a Paper

"On the Methods of Suppressing Sparking in Electro-magnets."

The object of the Paper was to classify the methods which have been suggested for the suppression of sparks in the circuits of electro-magnets and to call attention to a novel method of some importance.

The spark which is observed when the circuit of an electro-magnet is opened, sometimes called the extra-current spark, is due to the E.M.F.s of self-induction set up principally in the coils of the electro-magnet.

The author considered only the simple case where the self-induction in the rest of the circuit is small relatively to that of the coils of the electro-magnet, and he pointed out that while the E.M.F. and integral current on closing the circuit were perfectly definite, those arising when the circuit was broken were not so, as the resistance was variable and its law was unknown. There was also the complication due to the introduction of an arc. He observed, moreover, that in large electro-magnets with solid cores the mutual induction between the coil and the mass of the core retards the rise and fall of magnetisation, and therefore distributes the E.M.F.s due to self-induction, diminishing their amplitude and retarding their phase.

Prof. THOMPSON, after pointing out that the coefficient of induction of a coil was proportional to the product of the magnetic permeability by the square of the number of turns, and was independent of the current strength, while the magnetisation was proportional to the product of the number of turns by the current strength, proceeded to classify the devices employed to prevent sparking under the heads of "Mechanical Devices" and "Electrical Devices" respectively.

MECHANICAL DEVICES.

(*a*) *Simple Snap Switch.*—The advantage of a quick-acting break was due, in the author's opinion, to the surfaces being separated by a considerable distance before the E.M.F. attained its maximum value.

(*b*) *Breaking Contact in a Magnetic Field.*—A strong magnetic field appeared to have the effect of blowing out the spark.

(*c*) *Breaking Contact under the Surface of a Liquid.*—This appeared to prevent the formation of an arc, as an example of which, the author observed, that while it was very easy to get a fairly steady arc with an E.M.F. of 50 volts between carbons held in the hands, it became exceedingly difficult to do so when they were immersed in a liquid, such, for instance, as paraffin. He was not at all clear as to the reason of this action of liquids.

(*d*) *A Wiping Break with Asbestos or Brushes.*—Here the arc seemed to be wiped out as soon as it was formed.

(*e*) *Blowing out the Arc by a Current of Air.*—This method was the one employed in the Thomson-Houston system.

ELECTRICAL DEVICES.

(*a*) *The Use of Condensers:* (1) *Across Gap*; (2) *Across Terminals of Coil.*—Condensers had the effect of lowering the potential, and therefore the striking distance, and, where their capacity was greater than $\frac{4L}{R^2}$, converted the discharge into an oscillatory one.

(*b*) *Mutual Induction Protectors.*—(1). *Copper Sheath.* This was employed by Varley in 1867 and again by Brush in 1876. (2). *Layers of Foil between the Windings.* This method was patented by Paine and Frost in 1870, and re-discovered by Prof. Arons in 1887.

(*c*) *Short-Circuit Working.*—This was well adapted for constant-current circuits, but it did not suppress the sparking due to the self-induction of the rest of the circuit.

(*d*) *Differential Winding.*—The defect of the last method was obviated by a differential winding, in which the electro-magnet was excited by breaking one of the opposing circuits, but it had the defect of requiring more copper.

(*e*) *High-Resistance Shunt* (*Non-inductive, or with R large in comparison with L*).—This method was very convenient when it was

Digitized by Google

desired that the potential difference at the terminals should not exceed a certain value, V. Let R be the resistance of the shunt on an electro-magnet of resistance, r, with a working current, C. Let E be the maximum E.M.F. allowable. On breaking the circuit the electro-magnet and the shunt would form a closed circuit, in which the current would simply die out, and therefore V would never be greater than E, provided R did not exceed the value $\frac{E}{C}$. For example, if $r = 100$ ohms, C = ·05 ampere, E = 300 volts, then R must not exceed 6,000 ohms. The shunt might be made either of thin wire or carbon.

(*f*) *Voltameter or Liquid Resistance.*—This method, as employed by d'Arsonval, consisted in placing a set of accumulators across the break, and was fairly effective for continuous currents; but it was not perfect on account of the polarisation capacity.

(*g*) *Multiple Wire.*—This was a novel arrangement, employed by Langdon Davies in his harmonic telegraph, and consisted in winding the magnet with a number of layers of fine wire connected in parallel arc. The effect of this was to make the time-constant different for different layers, so that on breaking the circuit the energy was dissipated by mutual discharges among the different layers.

The author stated that the sparking was greatly diminished even when four layers were employed, and with twelve or more layers it was almost entirely suppressed.

(*h*) *Electro-Magnet with Two Bobbins in Series or Parallel.*

DISCUSSION.

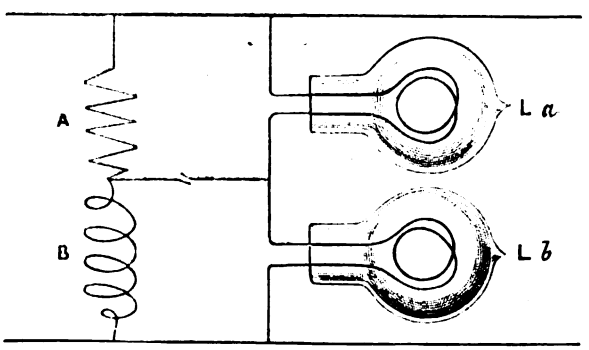
In the discussion which followed the reading of the Paper, Prof. AYRTON observed that it was important to remember that the E.M.F.s were due to the loss of magnetism, and as time was required for this to take place a quick-acting break would get beyond the sparking distance before the E.M.F. was developed. He thought the power possessed by liquids of hindering the formation of an arc might possibly be due to their cooling action. He also mentioned that Prof. Perry and himself had devised and described a non-sparking switch in which resistance was gradually introduced before breaking contact.

Prof. THOMPSON, in reply, stated that he had made a note of the switch referred to by Prof. Ayrton, but had not included it in his Paper, as in this switch the resistance of the circuit was varied in a determinate manner, and cases of this kind were outside the limits within which he had confined himself.

Mr. E. W. SMITH then read a Paper

"On a Shunt Transformer."

Suppose an alternating potential difference V to be maintained between two leads connected by a pair of resistances A and B in series. If A and B have the same impedance, then the potential



difference V_a and V_b at the terminals of A and B respectively will be equal if both the resistance and self-induction are equal in each, viz., $V_a = V_b = \frac{1}{2} V$. If, however, the resistance of A is large and non-inductive, while the self-induction of B is considerable, then V_a may still be equal to V_b, but V_a will be retarded while V_b will be accelerated.

Let the two leads be connected also by two similar sets of lamps, L_a and L_b, in series, as shown in the diagram. Then the potential difference at the terminals of each series would be $\frac{1}{2}$ V, but if the junction at the two sets is connected with the junction of the resistances A and B, the potential differences will become V_a and V^b respectively, and therefore each set of lamps will become brighter. The experiment was exhibited and the effect was very marked. The effect of joining the pair of junctions as described will be to increase the current through the inductive resistance as well as through the lamps, while diminishing the current in the main circuit.

The resistance A may consist of lamps, and B of a coil absorbing very little energy. The inductive resistance has been called by Prof. Ayrton a shunt transformer.

The author stated that he had made similar experiments with Mordey transformers, each wound with three coils, consisting of the same number of turns, one being used as the primary and the other two as independent secondaries. With one circuit comparatively non-inductive and the other inductive, the scalar sum of the amplitudes of the secondary currents was then greater than that of the primary, although the vector sum was of course less.

In conclusion the author pointed out the bearing of the experiment on the importance of devising some means of measuring the amount of energy supplied by electric lighting contractors, instead of merely the number of ampere-hours.

DISCUSSION.

In the discussion which followed the reading of the Paper Prof. S. P. THOMPSON suggested that the Paper afforded an argument against the employment of alternate currents for electric lighting.

Prof. AYRTON thought with the author that it accentuated the importance of devising some form of meter which would ensure the customers of the electric lighting companies getting what they paid for.

THE ELMORE COPPER PROCESS.

We print below an abstract of a report upon some tests of the Elmore process which were recently carried out at the works of one of the largest copper manufacturers in France under the superintendence of Mr. Stepney Rawson. The report itself, which we have had an opportunity of examining, is a very voluminous document, and bears evident traces of the care and skill which were expended to obtain accurate results. The summary, for which we are indebted to Messrs. Woodhouse and Rawson, is as follows:—

It is well known that the process consists of depositing copper, upon a rotating mandrel, from a sulphate of copper solution, but the valuable portion of the invention consists in the mechanical working of the surface of the metal from one end of the mandrel to the other by means of an agate burnisher under a few pounds pressure. By these simple means a remarkable change takes place in the constitution of the metal, which is now found to possess extraordinary strength, coupled with remarkable malleability, as may be seen from the results of the tests given below. The instruments used for arriving at the constants were a Charpentier ammeter and a Siemens potential galvanometer reading ·01 volts per degree. The dynamo was a 1 horse-power Gramme machine.

Work was carried on continuously for ten days with the exception of a short stoppage caused by an accident to the dynamo. The tubes are separated from the iron mandrels by pressure applied to the copper while the mandrel is being rotated in a lathe. The expansion of the copper is sufficient to enable the tube to slide off easily; but in regular work the method of expanding the copper by super-heated steam will be employed, as it is simpler and cheaper. The mean current used was 56·7 amperes, giving a current density of rather more than 15 amperes per square inch of cathode surface. This very high-current density is no doubt possible on account of the use of the burnisher, and is more than twice the maximum found advisable in ordinary copper refining without the burnisher.

The difference of potential across each tank was taken separately, the average being 0·9 volt per tank. In connection with this point it may be remarked that the E.M.F. does not reach its normal point until after about 36 hours; at the commencement it is about 5 per cent. higher. Connection is made with the rotating mandrel by means of a brush pressing on its surface. Notwithstanding this the steadiness of the voltmeter was practically complete, and, in fact, there appears to be an electrolytic action constantly going on between the brush and the surface of the mandrel, which tends to keep the contact remarkably perfect. The electrical horse-power absorbed in the tanks and connections amounted to 0·28 horse-power, and the total copper deposited amounted to about 104lb.

A careful calculation, deduced from the known value of the mean current, showed a close agreement between the theoretical and the actual quantity of copper deposited. The thickness of copper deposited was 0·14in., which is at the rate of very nearly $\frac{1}{8}$ of an inch per week.

Exhaustive tests were made upon portions of the tubes after their removal from the baths. The metal had a breaking strain of 32·3 and 32·7 tons per square inch, with an elongation of 7·5 and 10 per cent. on 8 inches of length in the longitudinal and transverse direction respectively. In connection with the question of elongation, it should be remarked that in ordinary practice the ductility of a metal is gauged by its elongation in the test machine. With the burnished copper the ductility is very high indeed, whilst its elongation is relatively very small, a fact which shows that we are dealing with a new variety of the metal. This point was fully

Digitized by Google

demonstrated by Mr. W. Parker, of Lloyd's, in a Paper read before the Society of Arts, wherein he states that the ductility of burnished copper with a 13 per cent. elongation is greater than that of ordinary copper with an elongation more than three times as large.

The fracture of one piece in the testing machine was arrested the moment before it was completed, in order to display the extraordinary symmetry of the deposit; the metal begins to flow exactly at the centre, and shows almost precisely equal percentages of elongation on either side of that line. The annealed test pieces which, from the appearance of the metal, led to the conclusion that it had been overheated, gave a breaking strain of 15·4 and 14·8 tons, with an elongation of 23 and 31 per cent. on 8 inches.

It is well known that wire is made by this process, by taking a deposited tube and shearing off a continuous square strip, beginning at one end and continuing until the whole of the tube has been cut into one continuous length of copper strip. This does away with the numerous processes of re-melting, casting, and sawing up, by which all high conductivity wire is made.

Portions of the tube were drawn down from a thickness of 3·4 millimetres to 1 millimetre through 14 hard holes without annealing, instead of having to be annealed every few holes. A test of this wire gave a breaking strain of 35 tons per square inch. Another sample of the same diameter was annealed and then drawn through 15 hard holes to a diameter of 0·98 millimetres, giving a breaking strain of 32·4 tons per square inch. A portion of this wire annealed and drawn through 7 holes to a diameter of 0·53 millimetres, and then annealed again, gave a breaking strain of 20·4 tons per square inch, with an elongation of 35 per cent. on 4 inches of length. Another portion of the tube was annealed and rolled cold from 3·5 millimetres to 1millimetre thickness, and gave when finished 26 tons per square inch breaking strain.

In both the wire drawing and the rolling the metal showed very exceptional qualities as regards ductility, and the above figures are sufficient evidence of its extraordinary strength. In addition to this, however, some interesting experiments were made of its behaviour under the hammer. At first the opinion of the workman employed to make these tests was that nothing could be done with the metal on account of its hardness. In spite of this he was however perfectly successful in hammering a broad flange 2½in. in width, on the edge of which he hammered out a tongue ·012in., or less than $\frac{1}{10}$th of the ordinary thickness of the tube, without the slightest sign of a crack in the metal. The extraordinary quality of the metal was plainly observable by the way in which the workman showed his hesitation in going any farther with the test, and his final opinion openly expressed was that it was impossible to break it under the hammer.

Several other exceptional tests were made, all of which were successfully withstood. It is impossible to give any exact idea of the value of these tests to those unacquainted with the nature of copper working, but it may be remarked that the single fact of the possibility of hammering a flange in the tube of this metal without once annealing places it in an entirely different category to any other class of tubes in which the annealing necessary to enable the tube to be worked robs the metal of a large percentage of its strength, whereas the burnished metal remains unimpaired at the very point where strength is principally required.

In one respect the copper showed a very remarkable difference from the ordinary metal. There is a growing tendency among engineers to regard the elastic limit of the metal as the real test of its commercial value in the matter of withstanding strains. In this respect the burnished metal shows a very high result, the ratio of elastic limit to breaking strain being as high as 61 per cent., and an English test on a similar tube gave a figure as high as 82 per cent. There are many indications that the limit of the reduction of horse-power necessary for producing a given weight of copper has not yet been reached, but an inspection of the above figures will show what a small amount of motive-power is required to produce a ton of copper in the form of finished tubes. The tests were carried out in the works of one of the largest copper producers in the world, and therefore ample opportunities occurred for comparing the new type of metal with the ordinary type, and it was plain that in every respect the superiority of the new was fully recognised by men thoroughly capable of judging.

Electrical Production of Bleaching Powder.—The *Gas World* says that Mr. Charles Lever, of Altrincham, has succeeded in producing direct from natural brine, by means of electricity, bleaching powder, caustic soda, and a solution to be used in bleaching the finest and most delicate fabrics. This discovery is likely to have the effect of revolutionising the manufacture of bleaching powder and the bleaching industry generally.

TARIFF OF THE STANDARDISING LABORATORY AT GRENELLE.

The following is the tariff adopted by the Commissioners of the Standardising Laboratory at Grenelle:—

A. Tests resulting in a certificate.

5fr.—(1) Conductivity per kilometre of a metallic wire. (2) Conductivity of an electric light carbon.

10fr.—(1) Insulation resistance of a dielectric. (2) Constants of a metallic wire (diameter, conductivity, mechanical strength, flexibility). (3) Standardising commercial ammeters, voltmeters, electro-dynamometers, or any kind of galvanometer. (4) Constants of a condenser (capacity, insulation). (5) Standardising a standard cell (E.M.F. at a certain temperature). (6) Photometric intensity of an incandescent lamp in several azimuths. (7) Photometric intensity of a gas flame or other similar source of light. (8) Standardising a resistance at a certain temperature.

20fr.—(1) Insulation tests under various conditions. (2) Photometric intensity of an arc in various azimuths. (3) Electric light carbon tests (conductivity, fixity of arc, rate of consumption). (4) Test of a formed accumulator (E.M.F., capacity, curve of discharge). (5) Battery tests (variation of E.M.F. and of resistance under working conditions).

25fr.—(1) Standardising an "electricity counter" for continuous currents. (2) Standardising a resistance box at a certain temperature. (3) Cable tests (conductivity, capacity, insulation after 24 hours' immersion in a bath at 24°C.). (4) Test of a dynamo of 1 horse-power and under (E.M.F., resistance and characteristic curve).

50fr.—(1) Standardising a laboratory ammeter or voltmeter. (2) Testing a standard resistance (resistance and variation with temperature). (3) Testing a standard E.M.F. (E.M.F. and variation with temperature). (4) Tests of 1 to 10 horse-power dynamos.

100fr.—(1) Tests of 10 to 15 horse-power dynamos.

B. Tests made according to the directions and in the presence of the person concerned, and which do not result in a certificate.

	Half-day (1 to 4).		Whole day (4 to 8).
Tests without dynamo or accumulators	...10fr.	.....	15fr.
Tests with dynamo or accumulators	.....15fr.	.....	25fr.

C. Tests at reduced charges.

(*a*) Standardising sets of identical commercial ammeters or voltmeters: in sets of 5=25fr. the set; in sets of 10=45fr. the set.

(*b*) Standardising sets of identical "counters": in sets of 5=50fr. the set: in sets of 10=75fr. the set.

(*c*) Cable tests; a set of 4=50fr. the set.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 1, 1889.

We are now awaiting the decision of the United States Circuit Court at Pittsburg in the lamp suit of the Westinghouse Company against the Edison Company. In this case the Westinghouse Company, as assignee for the Consolidated Company, has brought action against one of the sub-companies in the Edison ranks for infringement of the Sawyer-Man patent on the carbon filament, made from fibrous or vegetable material. It is claimed, and was argued last week before the court, that the Sawyer-Man lamp, embodying such a filament in an "arch" shape, was perfected in March, 1878, and that the same result was not arrived at by Edison until 1879. The Edison plea to the contrary was that Edison began experimenting on the subject in 1877, prior to the professed invention of Sawyer and Man, and made use in his experiments of carbonised paper among numerous other things. He subsequently conducted an extended series of experiments with platinum wire and other materials for conductors, and was convinced from the beginning that carbon of some form, fibrous or otherwise, was the most desirable material for an incandescent conductor in a sealed globe, provided that the chamber had been so exhausted

Digitized by Google

as to maintain a stable vacuum. Edison finally achieved his well-known results, it is claimed, in the fall of 1879, and exhibited his lamp at Menlo Park, where he used a lamp such as is now employed everywhere, in which the filamental carbon, having high resistance to the passage of the electric current, is secured in a glass globe sealed up by fusion of the glass from which the air had been exhausted to a state of high vacuum. To obtain this result, moreover, he had followed the method of operating the lamps in parallel, whereas Sawyer and Man sought to use low-resistance filaments, involving a resort to the series method. Mr. Edison finally settled down to bamboo fibre, as the result of experiments which cost hundreds of thousands of dollars, and which he ultimately selected after sending agents all over the world to get bamboo of just the necessary structure. While the original Edison lamp was thus publicly exhibited at Menlo Park to everybody, the original Sawyer-Man lamp was shown to nobody, and such lamps as were subsequently shown were practically worthless. To this was replied, that although Mr. Edison had been credited with the invention of the entire incandescent lighting system in vogue to-day, that system did not become practicable until after Sawyer and Man had discovered the suitable fibre. The statement that the Sawyer-Man lamp would not burn was incorrect, as it had been fully tested and found to burn for 150 hours. After the Court had heard the arguments it took the papers and reserved its decision. One of the particular claims in the Sawyer-Man patent on which the suit is based is for "an incandescing conductor for the electric lamp of carbonised fibrous or textile material, and of an arch or horseshoe shape, substantially as hereinbefore set forth." It will be observed that this is a very broad claim, and that it covers the essential features of the Edison lamp. A similar suit has been going on before the Circuit Court in New York, bringing out the same evidence as has been adduced in the Pittsburg suit, and rehearsing facts which have now become an old and worn story to everyone acquainted with the subject of incandescent lighting and the litigation of it. The importance of this suit at Pittsburg is that it apparently brings the matter nearer to a final adjudication than it has ever before reached in this country; but it is understood that whichever way the case goes the losing parties will immediately appeal to the United States Supreme Court.

That we are gradually improving in our methods of indoor wiring may be inferred from the statements which have just been made by Inspector M'Devitt of work done in the city of Philadelphia. Mr. M'Devitt has the supervision of electrical construction there, and his report for last year shows that the element of danger has practically disappeared. He says that during the past year not a single dollar has been paid for damage by fire caused by electricity, in spite of the fact that the section of which he writes embraces over 1,300 houses which are using current. Some of these buildings, moreover, have been wired for upwards of eight years, a fact which certainly speaks well for the construction and the subsequent inspection at the time. A report of equally encouraging nature comes at the same time from Chicago, where last year a total of 2,369 arc lamps and 17,717 incandescents was inspected, which, added to 22,756 lamps inspected during the previous year, made a total to January 1st, 1889, of 42,842 lights. The report states that during the year a marked disposition to improve the standard of installations has been manifested, and, as an evidence of the feeling on the subject, it is added that at a conference held recently to consult on the subject an unqualified condemnation of the cheaper insulations, especially that known as "underwriter's," was unanimously expressed by the representatives of all the principal companies doing an arc and incandescent business in Chicago It is interesting to note also that at the beginning of the year there were 53 motors in use in Chicago, ranging from $\frac{1}{8}$ to 15 horse-power,

The Bill for increasing the American Bell Telephone Stock from $10,000,000 to $20,000,000 has now been passed in the Massachusetts House and Senate, and the company will therefore be well provided with funds for carrying out some of the larger schemes which it has in contemplation, such as the erection of its new building in Boston and the extension of its long-distance telephone service in the West. As might be expected, the company encountered some opposition in this matter, but by no means so much as they experienced before when a similar move was undertaken. The company will have no difficulty whatever in selling such of the stock as it may choose to put on the market. The present price of Bell Telephone Stock is about 240, which is sufficient to show that there will be an eager demand for all that may be placed within the public reach. Although Bell Telephone Stock is regularly quoted, and there is a more or less active market in it, it does not appear that at any time a very large number of shares exchange hands now.

CORRESPONDENCE.

THE TERMINOLOGY OF ALTERNATING CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is much to be hoped that the confusion from which acoustics and optics have recently escaped is not about to settle upon electricity. In the former sciences "period," or "wave," refers always to the complete cycle of changes; and the number of complete periods in the unit of time, say, one second, is (after Thomas Young) called the "frequency." The same terminology is applicable to electrical vibrations. The period, or periodic time, will of course cover one positive and one negative part; and in like manner the "periodic frequency" will mean the number of periods per second. When the usage is well established, it may be possible to drop the qualifying "periodic," and to speak simply of frequency; but in electricity there may be at first some danger lest the frequency of alternating currents should be taken to mean the frequency of *alternation*. For this reason it will be prudent for the present to speak always of *periodic frequency*.—Yours, &c.,

RAYLEIGH.
WILLIAM THOMSON.

Terling-place, Witham, Essex, June 11, 1889.

SELF-INDUCTION IN ALTERNATING-CURRENT MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your leaderette in your last issue you regret that Dr. Hopkinson did not bring his discovery forward sooner, and mention Mr. Kapp and Prof. Forbes' names as being identified with the theory that alternate motors depend on self-induction. May I offer a slight correction. Dr. Hopkinson devoted the larger part of a Paper at the Society of Telegraph Engineers to the investigation of the effect of self-induction in making machines synchronise.

His Paper is painfully mathematical. The action of self-induction was explained in English by me in some articles on Electrical Measurement in 1887, and I certainly regarded the theory as well known then. I may add that I see nothing in Mr. Mordey's interesting experiments which conflicts with the recognised theory; in fact, the position of synchronous motors is not altered, and the strictures in my articles on testing alternating dynamos and motors seem to me still to hold good.—Yours, &c.,

JAS. SWINBURNE.

Wimbledon, June 11, 1889.

[Our correspondent has slightly misunderstood the purport of our note. The position which we were attempting to elucidate appears to us to be this: (1) Prof. Forbes and Mr. Kapp have recently insisted upon the supreme importance of the presence of self-induction in the working of alternators in parallel. (2) Mr. Mordey has shown that very little self-induction—apparently much less than that demanded by Mr. Kapp—is necessary. (3) In 1884, however, Dr. Hopkinson gave a well-nigh complete solution of the problem, with expressions from which the best value of L in a given case might readily be deduced. We regret that we are not well acquainted with Mr. Swinburne's work of 1887 in this particular direction—the greater part of his valuable book we know well—but we shall take the earliest opportunity of remedying this deficiency. —ED. *E.*]

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

May 21, 1889.

8,390. W. M. MORDEY. London. Improvements in electric motors.

8,400. J. M. PORTER. Leeds. An improvement in electric bells.

8,451. G. GALLOP. London. Improvements in conduits for electric light and other wires.

8,453. W. M. MORDEY. London. Improvements in regulating electric currents.

8,456. L. BRISTOL. London. Improvements in portable electric safety lamps.

8,459. T. L. WILLSON. London. Improvements in dynamo electric machines and electric motors.

8,460. G. FR..NCE and E. HOLROYD. London. Improvements in coating and protecting wires for electrical, telephonic, and other analogous purposes; also applicable in the manufacture of tubing.

8,468. T. D. HOLLICK. London. Improvements in tramcars, locomotives, or other vehicles driven by electricity.

May 22, 1889.

8,493. W. J. S. BARBER-STARKEY. Manchester. Improvements in automatic cut-outs for electric circuits.

8,528. J. HOPKINSON. London. Transmission of power by alternate electric currents and apparatus therefor.

May 23, 1889.

8,557. M. PARKER. London. Improvements in or relating to meters or instruments for measuring currents of electricity.

8,559. W. OSBORNE and J. S. SCALES. Tonbridge. Improvements in securing telegraph wires to insulators.

8,588. J. SWINBURNE. Wimbledon. Improvements in alternating-current dynamos and motors.

8,606. M. BAILEY and J. WARNER. London. An improved form of secondary battery for the use of miners and the like, and lamp mount for same.

8,619. A. SIEGMANN. London. An improved electrical alarm for audibly indicating and announcing the varying water levels of steam boilers and the like.

May 24, 1889.

8,631. R. THOMPSON and H. J. PYNE. Liverpool. An improved portable electric lamp and battery.

8,657. E. B. BRIGHT, F. W. ENGLEBACH, and J. B. BRIGHT. London. Improved methods and appliances for conducting and distributing electric currents.

8,674. J. HOPKINSON. London. Improvements in connection with electrical tramways or railways.

8,692. J. E. KINGSBURY. London. Improvements in multiple switch board systems for telephonic exchanges and wire bands to be used therein (The Western Electric Company, United States).

May 27, 1889.

8,697. S. H. GIBSON. London. Improvements in electric musical mechanism.

8,709. E. H. M. ANDREOLI. Brixton. Amalgamating gold by electricity and mechanical motion.

8,730. A. M. CLARK. London. Improvements in printing telegraphs (W. F. Johnson, United States).

8,769. A. C. COCKBURN and J. N. COOPER. London. Improvements in electrical measuring instruments.

8,780. E. M. DE FACIEN. London. Improvements in electrical switches.

8,793. W. H. WINNALL. London. Improvements relating to screw-cutting lathes and to electrical indicating apparatus for use in connection therewith.

8,800. H. H. LAKE. London. Improvements in regulators, chiefly designed for use in electric arc lamps (O. H. L. Lindemann, Germany).

May 28, 1889.

8,815. W. P. THOMPSON. Liverpool. Improvements in devices for automatically interrupting an electric circuit under pre-determined conditions (The Westinghouse Electric Company, United States).

8,855. T. HARRIS and H. F. DE B. CAMERON. United States. Improvements in secondary batteries or accumulators.

May 29, 1889.

8,905. A. G. BURRELL. Sheffield. Receiving and transmitting an electric current for telephonic, telegraphic, or other electrical purposes, viz., "The anti-alternate current relay."

8,925. C. WELLS. London. Improvements in electric batteries.

8,935. A. CASSERINI. London. For an invention for electricity employed as agent for destroying rabbits and other animals prejudicial to agriculture.

8,944. D. C. BATE. Dulwich. Improvements in electrical switches or commutators.

8 958. A. FRAGER. London. An electric meter.

May 30, 1889.

8,973. F. BOSSHARDT. Manchester. Improvements in the method of and means for collecting and storing electrical energy (V. Hoeft and Co. and R. F. Verdier, Belgium).

8,979. F. V. ANDERSEN. London. Improvements in electric switches.

8,986. D. URQUHARDT, W. BATES and F. WYNNE. London. Improvements in secondary batteries.

8,999. J. HOPKINSON. London. Improvements in electrical tramways or railways and apparatus therefor.

May 31, 1889.

9,034. W. PRESSLAND and W. T. PRESSLAND. London. Improvements in self-contained dome electric bells.

9,074. R. WARWICK. London. Improvements in the electric ignition of gas.

June 1, 1889.

9,093. A. JUNG. Liverpool. Improvements in storage batteries.

9,096. H. F. JACKSON and D. SINCLAIR. Glasgow. Improvements in telephonic switch-boards.

9,119. E. F. FIFORD. London. Improvements in electric bells.

9,133. H. H. LAKE. London. Improvements in the manufacture of carbons or electrodes for electric lamps (Lacombe and Co., France).

June 3, 1889.

9,153. D. J. ARNOLD and H. B. CORYELL. London. An improved dry galvanic battery.

9,162. C. E. L. BROWN. London. Improvements in the armatures of dynamo machines.

9,163. L. B. MILLER. London. Improvements in electricity meters or apparatus for measuring electricity, partly applicable for other purposes.

9,166. D. WELLS. Edinburgh. An improved electrical repeater and commutator to indicate the normal position and the movements of railway or other signals, slots or the like.

9,182. A. GRAHAM. London. Improvements in apparatus or devices for switching or diverting electric currents, more especially intended for use with telephonic circuits.

9,183. M. SUSSMANN. London. An improved exciting liquid for electric batteries.

9,192. W. W. STRODE and W. DAVIS. London. A new or improved fitting for electroliers.

9197. H. SUBLINER. London. Improvements in and relating to relays for telegraphic purposes.

June 4, 1889.

9,231. W. E. HEYS. Manchester. Improvements in the method of and devices for regulating currents generated by shunt-wound dynamo-electric machines (E. P. Clark, United States.)

9,237. G. E. DORMAN. Stafford. Improvements in dynamo-electric generators and motors.

9,238. R. H. COURTENAY. London. Improvements in micro-telephonic apparatus.

9,241. A. A. C. SWINTON. London. Electric meters.

9,258. F. L. RAWSON and W. S. RAWSON. London. Improvements in electric signal lamps and appliances connected therewith.

9,294. H. H. LAKE. London. Improvements in and relating to dynamo-electric machines and electric motors (C. S. Bradley, United States).

9,300. H. H. LAKE. London. Improvements in and relating to dynamo-electric machines (H. Lemp, United States).

9,304. W. BARNICOAT. London. Improvements in switches for electrical purposes.

June 5, 1889.

9,350. J. JOHNSON and F. RUSSELL. London. Improvements in dynamo-electric machinery.

9,352. F. ESPIR (agent for P. Klotz). London. Improvements in electrical horology (L. Belzon Fils, France).

9,376. H. J. HARRIS. London. Improvements in miners' electric lamps.

June 6, 1889.

9,397. H. W. C. COX. London. Improvements in electrical thief detectors.

June 7, 1889.

9,440. E. W. J. MACDONALD. London. Improvements in ceiling roses for suspending electric lamps and other electrical purposes.

9,445. J. W. SEE. London. Lightning arresters for electric conductors.

9,456. B. M. DRAKE and J. M. GORHAM. London. Improved method for preventing fumes from secondary batteries.

9,461. D. MCINTOSH REID. London. Improved composite electric omnibus.

9,496. F. MARX. London. Improvements in the accumulation of electrical energy and apparatus therefor.

June 8, 1889.

9,508. E. A. SPERRY. London. Improvements in arc lamps and in dynamos to be used therewith.

9,509. E. A. SPERRY. London. Improvements connected with electrically operated coal-mining and drilling machines.

9,528. H. COLES. London. An improvement in telephony.

COMPANIES' MEETINGS & REPORTS.

Lancashire and Cheshire Telephonic Exchange Company (Limited).

The eighth ordinary general meeting of the shareholders of this Company was held on Tuesday last at the Memorial Hall, Manchester, Mr. Alderman Joseph Thompson, Chairman of the Directors, presiding.

The Directors' report and statement of accounts, already published, were taken as read.

The CHAIRMAN moved their adoption and the declaration of a dividend at the rate of 8½ per cent. per annum for the ten months ending 30th April. This, he said, was the largest dividend the Company had ever declared, and it was the largest the Company had ever made.

The motion was seconded by Mr. ELI HEYWORTH (Blackburn), Deputy-Chairman of the Company, and adopted.

The meeting was then made an extraordinary general meeting, for the purpose of submitting the following resolutions for confirmation:—

(1) "*That the Agreement submitted to this meeting, and expressed to be made between this Company and the National Telephone Company (Limited), for the Amalgamation of the two Companies, by a transfer of the business and property of this Company (with certain exceptions) to the National Telephone Company (Limited), in consideration of shares in that Company be, and the same is, hereby approved.*"

(2) "*That with the view of giving effect to the above-mentioned Agreement, and in order to enable the shares to be allotted thereunder to be distributed among the members of this Company, this Company be wound up voluntarily, under the Companies' Acts, and that Thomas Abercrombie Welton be, and he is hereby, appointed liquidator for the purpose of winding up its affairs and distributing its property.*"

(3) "*That pursuant to the 161st section of the Companies' Act, 1862, the liquidator be, and he is hereby, authorised to carry the said Agreement into effect, and to receive the shares agreed to be allotted thereunder, and to distribute the same in specie among the members of this Company.*"

The CHAIRMAN said there was an old saying that union was strength, and the Lancashire and Cheshire Company, and the other telephone companies of the kingdom, had for some time back felt that they would be in every way much better off if they were to be united on equitable terms. The Directors had come to the conclusion, after very careful thought, that in every way it would be advantageous to the Lancashire and Cheshire Company to amalgamate with the other two companies—the United Company (the parent company) and the National Company. They thought the amalgamation would result in the reduction of the working expenses by a very considerable amount. In the second place, they thought there would be the advantage of having the opinion of skilled persons who had given their thought to telephonic development, and who represented different portions of the country; and they thought that by amalgamation they could work together profitably as one board. Then they thought the adoption of the proposal would result in developing the telephonic system very largely indeed. Their Company had already an extensive trunk system in the two counties, and the Directors believed that with the march of science the time was not far distant when telephonic messages might be easily sent to great distances. It would be manifestly advantageous for the Stock Exchanges of our great centres of population to be put in telephonic communication one with another. Then the shareholders had also to look at the matter as one of self-interest. The intention of the three companies in their union was to have formed a new company, and this new company was to buy up the three existing companies, and probably by-and-bye to buy up the subsidiary companies. Everything was arranged between the three companies, but at the last moment the Postmaster-General declined to grant a license to the new company. Before he went further perhaps he might say that they had spent twelve months in trying to come to a basis of agreement. It was thought at first that the best way would be to submit the books of the three companies to a first-class firm of accountants, and in that way ascertain on what terms each company should be taken in. But after twelve months of labour they found that they were no further forward than they were before, and the Directors began to think whether there was not a better way. Mr. Charles Agnew, one of the Directors, suggested that the fairest and simplest way would be to take the market value of the different stocks on a certain date. That idea was also broached in London, and it was ultimately adopted. But when everything had been arranged on this basis the Postmaster-General was approached, and was asked if he would grant a new license. This he distinctly refused to do, and for a time it appeared as if they were to be baffled in their efforts. But the solicitors looked into the matter and found that there was full power for any one of the existing companies to absorb the other two, and the company which was thought to be the most suitable to do so was the National Company. That company had a good name, and it covered the whole country. It was also in favour of that company absorbing the other two that the par value of its shares was £5, and the market value only £6, whereas if the United Company had been taken as a standard, their shares, which stood in the market at £15, would have had to be reduced to £5, because £5 was the nominal value. The nominal value of the Lancashire and Cheshire Company's shares being only £1, they were, for the purpose of which he was speaking, in a worse position

than either of the other two. It had since been arranged that the agreement should be so far modified that the market value of the shares should be reduced by one-sixth—that the United Company's should be taken at £12. 10s., the National Company's at £5, and that the Lancashire and Cheshire Company's, which stood in the market at £1. 11s. 4d., should be reduced to £1. 6s. 3d. Although that seemed to be a reduction in the value of the shareholders' property, it was not so in reality. Although it decreased the nominal amount, it increased the dividend on the shares, and the moment it was known on the market that the shares were earning a larger dividend they would go up to the old value. Therefore, when it was suggested that the value of the share should be reduced to £1s. 6s. 3d. it was only a nominal matter, and they would get the full value of their shares if they wished to sell. He had no doubt they had seen that the Postmaster-General had expressed dissatisfaction with the action of the companies in this matter. It would almost seem as if they existed on sufferance from the Post Office. The Postmaster-General would not allow them to transmit the cotton market from Manchester to Liverpool, and he would not allow their athletic friends to telephone the result of a cricket match from Old Trafford to Manchester, because to do that was to transmit news, and the Post Office derived a certain revenue from that source. But surely that was, after all, crippling a legitimate business. The telephone companies did not exist on sufferance from the Post Office, which did nothing to develop their business. It only gave them a license to work, and for that it exacted from them a large royalty. He found that the three companies about to be amalgamated paid to Her Majesty's Post Office £35,000 a year in royalties for which the Post Office did nothing at all except to send their clerks to examine the telephone companies' books to see that the companies did not cheat. In return for what they contributed to the revenue they had got a letter from the Postmaster-General saying that he disapproved of the scheme. The companies, after all their trouble and outlay, were entitled to fair consideration, and ought not to be treated in the manner they had been. The *Economist* of June the 8th spoke of the scheme of amalgamation as one directly hostile to the public interests, but the promoters of the amalgamation maintained on the contrary that it would be advantageous to the public. As a trading company, their property depended on how the public were satisfied with the manner in which they served them. He did not hesitate to say that by amalgamation they would have a larger capital at their command to develop their business, and their endeavour would be to serve the public as well in the future as in the past. A number of their patents would soon lapse, and competition might be started, and it behoved them to set their house in order, so that when the patents lapsed the public might not want to go to some other company. Let it be remembered that they were liable to competition at any time. There was nothing to prevent any other company starting provided they could get a license from the Post Office. Under amalgamation they would not have so much to fear from competition. He thought they would be able to reduce their charges by-and-bye, and to render the public more efficient service in the future than they had done in the past. Certainly it was the wish of the Directors to make the service as cheap and efficient as they possibly could. He concluded by moving the adoption of the resolutions as given above.

Mr. ELI HEYWORTH seconded.

In reply to a question by Mr. EDWARD CROSS, the CHAIRMAN said the Company's license did not lapse till the year 1912. So long as they did not break its provisions in any way, and they would be most careful not to do that, the license could not be withdrawn. The amalgamated company would have a right to go into any part of the kingdom.

Mr. J. E. LONGSON supported the motion for the adoption of the report. The Directors, he said, were deserving of great credit and the thanks of the shareholders for the efforts they had made to bring about this scheme of amalgamation.

Mr. JOSHUA OPENSHAW asked what it was proposed to do with reference to the position taken up by the Postmaster-General.

The CHAIRMAN said that in the action they had taken they had been fortified by the advice of three of the best counsel on the subject of public companies. He had no fear whatever as to the action of the Postmaster-General on the major question, although in minor matters there might be vexatious interference. If there was such interference they could enlist the services of the local members of Parliament, and get the matter brought before Parliament.

In reply to further questions, the CHAIRMAN said it was understood that in addition to the Central Board there would be local Boards of Directors. One advantage of amalgamation was that there would be more money at disposal. The Directors of the Lancashire and Cheshire Company had had a great deal of trouble and anxiety as to finances, not from the untrustworthiness of the Company, but quite the contrary. They had increased their business, and they saw a large increase in the future; but where was the money to come from? They could not issue another share without the consent of the United Company, who had them in their grasp. Any shareholders who did not wish to continue to hold the shares after amalgamation would receive the market price of their shares.

The motion was then put to the meeting and adopted.

A vote of thanks to the Directors brought the proceedings to a close.

NEW COMPANIES REGISTERED.

ELMORE'S FOREIGN AND COLONIAL PATENT COPPER DEPOSITING SYNDICATE (LIMITED).—The prospectus of Elmore's Foreign and Colonial Patent Copper Depositing Syndicate (Limited) states that this company has been formed to acquire the foreign patent rights relating to the extremely valuable discovery made by Messrs. Francis Edward Elmore and Alexander Stanley Elmore for manufacturing copper articles direct from rough copper bars, which does away with the processes of melting, rolling, forging, drawing, &c., and the present costly and laborious methods of manufacturing copper articles, such as tubes, vats, cylinders, pans, printing rollers, wire for electric purposes, and a vast number of other articles too numerous to mention. The capital of the company is £120,000, divided into 15,000 priority shares of £5 each, and 9,000 founders' shares of £5 each. Of the above, 3,250 priority shares and 650 founders' shares have already been applied for by the directors and their friends, and will be allotted in full; 11,750 priority shares and 2,350 founders' shares are now offered for subscription. The shares are payable:—10s. on application, £1. 10s. on allotment, £1. 10s. on the 1st. August, 1889, and £1. 10s. on the 1st October, 1889. The 3,000 founders' shares are reserved for allotment exclusively amongst applicants for priority shares, in the proportion of one founders' share for every five priority shares allotted, and the remaining 6,000 founders' shares will be allotted to the vendors. The Directors are—Sir John H. Morris, K.C.S.I., Edward J. Carson, Esq., John Macfarlan, Esq., J. Jephson Atkinson, Esq., John T. Cooper, Esq., Frederick L. Rawson, Esq., M.I.E.E., and William Elmore, Esq. It is not intended that the present Company should work the process, but that it should resell the patents by the formation of subsidiary companies for different countries, and negotiations have already been commenced with a view of selling the patents for all foreign and colonial countries to one group, on terms which point to the shares of this Company receiving quite unusual returns at a comparatively early date. The price paid for the English patents was £100,000 in cash and shares. The amount to be paid by the company is £110,000, of which £30,000 is payable in Founders' Shares, and the balance in cash. The vendors pay all preliminary expenses up to the first allotment of shares.

THE MUNICIPAL ELECTRIC LIGHT AND POWER CORPORATION (LIMITED).—Registered by W. Webb and Co., 6, Essex-street, Strand, W.C., with a capital of £25,000 in 2,490 shares of £10 each, and 100 founders' shares of £1 each. Object, to generate, produce, supply and use in any manner electric or magnetic currents for the purposes of providing light, heat, motive power, &c. There shall not be less than three nor more than seven directors. Qualification, 25 shares of £10 each.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 7, 1889, amounted to £4,689.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended June 7, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,230.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

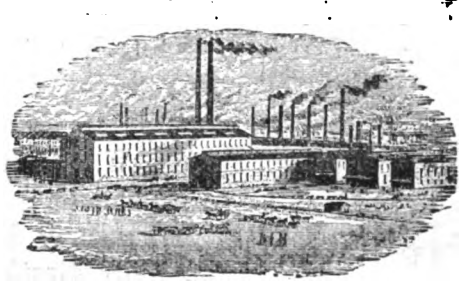
This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.



FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 579.—Vol. XXIII. FRIDAY, JUNE 21, 1889. Price Fourpence.

NOTES.

The deputation which waited upon Sir Michael Hicks-Beach on Wednesday last had so good a case that, even had the duty fallen to less able spokesmen, it is scarcely conceivable that the Government could turn a deaf ear to their plea. The facts were clearly and succinctly stated in the letter of Lord Crawford and in the speeches of Lord Rayleigh, Sir William Thomson, Sir Vincent Barrington, and of Mr. Crompton. And the said facts simply amount to this—that in the absence of an official or officially recognised standardising laboratory the industry is powerless to fulfil the requirements of the Board of Trade, which it is bound by statutory enactment to obey. That it is the duty of Government to make a way through this *impasse* is a point which scarcely requires argument. That such a laboratory will also be of immense benefit to the industry at large is almost equally self-evident.

Honour to whom Honour is due! Now that the question of the Standardising Laboratory has entered upon its final stage and is tending towards an issue which it is impossible to doubt will be completely successful, it would be ungrateful not to recognise the fact that to Dr. Fleming more than to any other single individual is due the merit of publicly initiating the movement, and of quietly but persistently keeping it before the leaders of the scientific world. It was in November, 1885, that Dr. Fleming first directed attention to the question, by an able Paper read before the Society of Telegraph Engineers "On the Necessity for a National Standardising Laboratory for Electrical Instruments." As shewing the interest which the question awakened at that comparatively early date, it may be mentioned that no less than eighteen speakers took part in the discussion. Mr. Preece delivered an able and interesting speech, in which he strongly supported the movement, and amongst the visitors who spoke were Mr. Chaney, Chief of the Standard Department of the Board of Trade, and Mr. Whipple, of Kew Observatory. It is desirable, perhaps, to call attention to the fact, however obvious, that much if not all of the practical value of the laboratory will depend upon the man who is entrusted with the technical supervision of the establishment.

The second Conversazione of the Royal Society for the present session—being a Ladies' night—was, we need scarcely say, a brilliant success. The electrical exhibits were not as showy as is sometimes the case, but all were full of interest. The chief novelty was undoubtedly the improved form of the Grove Gas Battery, devised and exhibited by Mr. Ludwig Mond and Dr. Carl Langer; the device is decidedly ingenious, and may possibly prove of some economic value. In this cell the plates consist of a porous material, which has been impregnated with dilute sulphuric acid, and is built up on a leaden grid. Both surfaces are next coated with platinum foil, first pierced with innumerable fine holes and then covered with a thin film of platinum black. These coatings are insulated from one another, but are each in contact with a portion of the grid, which is made in two halves, placed back to back with the porous material filling the space between. A number of these elements are placed side by side, and air passages are so arranged that hydrogen can be passed between every alternate pair, and air along the others. The process of charging the battery, therefore, consists merely in passing those gases through until the finely divided platinum can absorb no more. The results are described by the inventors as follows:—

"One element, with a total effective surface of 774 square centimetres = 120 square inches, which is covered by 1 gramme of platinum black and 0·35 gramme of platinum leaf, shows an electromotive force of very nearly 1 volt when open, and produces a current of 2 amperes and 0·7 volt or 1·4 watt, when the outer resistance is properly adjusted. This current is equal to nearly 50 per cent. of the total energy obtainable from the hydrogen absorbed in the battery. The electromotive force decreases, however, slowly, in consequence of the transport of the sulphuric acid from one side of the diaphragm to the other. In order to counteract this disturbing influence the gases are from time to time interchanged. The battery works equally well with gases containing 30 per cent. to 40 per cent. of hydrogen, such as can be obtained by the action of steam, or steam and air, on coal or coke, if these gases have been sufficiently purified from carbonic oxide and hydrocarbons. The water produced in the battery by the combination of hydrogen and oxygen is carried off by the unconsumed nitrogen and an excess of air carried through it for this purpose."

Prof. S. P. Thompson repeated the experiment of magnetically rotating the plane of polarisation, and analysing by means of the eye of a cod, which he showed recently at the Physical Society. He also repeated the beautiful experiment of Röutgen, showing the expansion and contraction of the rings seen in quartz by convergent polarised light when the quartz plate is transversely electrified. Prof. Thompson's contribution further included some very fine illustrations of cobalt-plating by a new process of his own. Cobalt promises several advantages over nickel as a plating metal as soon as the demand is sufficient to reduce the price. Dr. J. A. Fleming exhibited some incandescent lamps arranged to show the so-called Edison-effect.

Digitized by Google

It will be remembered that this consists in showing that if a lamp has a platinum plate carried on a wire sealed through the glass, placed between the loop when the lamp is in action, it is found that a galvanometer connected between the middle plate and the *positive* side of the carbon loop shows a current passing. If the galvanometer is placed between the middle plate and the *negative* side of the loop no current is found. The lamps exhibited shewed this effect very well. By shielding the negative leg with a glass or metal tube the effect is entirely stopped—so that is evidently due to convection either of carbon particles or of the residual gas. Dr. Fleming has carried out a series of experiments which have led to results of a curious character, and will no doubt form the subject of a future Paper.

By a somewhat singular coincidence, just at the time when the relations between the Telephone Companies and the Government are exciting attention in this country, the same question has become the subject of bitter controversy in Paris. In this case the facts may be briefly given as follows:—In 1879 the French Government granted a concession conferring the right of working Telephone Exchanges in France to La Société Générale des Telephones for a period of five years. In September, 1884, this concession was renewed for a further period of five years. In return for the privileges granted, the Company agreed to pay the State 10 per cent. of the gross receipts, and a like sum to the Municipality of Paris for the right of running their cables in the city sewers. The concession not only afforded no monopoly to the Company, but empowered the State to determine the agreement at any time by purchasing the whole undertaking for a sum to be fixed by experts. The Company has, up to now, expended fourteen millions of francs, and has paid an average dividend of 4¼ per cent. to the shareholders. It is now proposed that the Government should acquire and complete the existing telephone systems for a sum not exceeding ten millions of francs. Considerable dissatisfaction is naturally expressed that a suggestion of an openly confiscatory character should have been made; but perhaps the blame chiefly rests with those who originally entered into such an extraordinary arrangement. However harsh the action of the Government may appear, it would seem to be quite within the terms of the agreement.

The meeting of the American Institute of Electrical Engineers, which has just taken place in New York, would appear to have been one of the largest and most successful gatherings of that body which has yet been held. The presence and active support of such men as Prof. Rowland, Prof. Nichols of the Cornell University, and Prof. Elihu Thomson lent additional importance to the proceedings. Prof. Rowland delivered an address on "Modern Views in Respect to the Nature of Electric Currents," which will be read with the deepest interest on this side of the Atlantic. In this address the remarkable theoretical and experimental advances of the last year or two were presented with a freshness and grace of diction, combined with a studied simplicity, which it would be difficult too highly to admire. Prof. Nichols presented Papers, by students of the Cornell University, "On the Efficiency of the Arc Lamp," "On the Personal Error in Photometry," and "On the use of the Copper Coil Voltameter," all of which will well repay perusal. Prof. Elihu Thomson read a Paper on "Magnetism in its Relation to Induced Electro-Motive Force or Current," in which the ideas, if not invariably novel in themselves, are frequently expressed in a manner which will be quite fresh to the majority of our readers. We must also mention a very valuable Paper by Mr. W. H. Peirce, "On the Relation between the Initial and Average Efficiency of Incandescent Lamps," a subject of very great practical importance on which little or nothing has hitherto been made known.

The paper of Mr. Crocker, on Motor Regulation, presents a good summary of all the possible—and some of the impossible—ways of dealing with that interesting problem, so far at least as regards continuous-current motors. It will be seen that Mr. Crocker himself rather favours the idea of obtaining regulation by moving the armature bodily along the line of its shaft. In the absence of actual experience we confess that we should have supposed that this device would have a tendency to disturb the field of the machine, and thus to set up sparking. However this may be, it is a singular coincidence that on page 136 of the same issue in which we reprinted Mr. Crocker's Paper we had occasion to speak of the very early magneto machine of Woolrich, the Birmingham electro-plater. Now, on referring to his patent (No. 9,431 of 1842), it will be found that he described this very device of shifting the armature in order, in this case, to regulate the current. It would therefore appear highly probable that this is the earliest method of regulation applied to dynamo-electric machinery in general which is to be found on record.

Several trial trips have recently been made on the North Metropolitan Tramway Company's lines with an electric car and tender embodying the ideas of Mr. W. D. Sandwell, of the Victor Engineering Works, Holloway. In addition to his method of gearing, which possesses some novel features, the chief points of Mr. Sandwell's system are the employment of a single motor with two armatures and of a separate trolley for the accumulators, the motor being placed under the car itself. The motor, which has field magnets of the Siemens double magnetic circuit type and a Gramme armature, drives by a leather chain belt upon one or the other of two pulleys fitted to double shafting, the shaft of one pulley being hollow and fitting over that of the other. Upon this shafting are two small toothed wheels, gearing into two larger toothed wheels of different diameters on the car axle, so that by shifting the belt from one pulley to the other it is possible to obtain a considerable variation in speed. By this combination it is sought to gain the advantages of belt gearing for the high-speed transmission and of toothed gearing for the low speeds. The belt used on the experimental car has been severely tested, and has proved very satisfactory. The field magnets are mounted on a slide, and can be changed from one armature to the other by a few turns of a lever. This arrangement no doubt has its advantages if it can be shown that a motor armature, however well designed, is so much weaker than other parts of the apparatus that duplica-

Digitized by Google

tion is a necessity. By employing a separate trolley for the storage cells Mr. SANDWELL lessens the amount of alteration required to adapt an ordinary tramcar to electric working, and completely obviates all danger of damage to the motor from leakage or spilling of acid, in addition to simplifying the operation of charging. The motor takes an average current of 40 amperes when running at 700 revolutions, and giving about 7·5 horse-power on the brake. The battery consists of 68 E.P.S. cells of the latest traction type, with a capacity of 140 ampere hours. The weight of the motor and gearing is something over half a ton, of the trolley and battery two tons, of the car three tons when light and nearly six tons when loaded. It is anticipated that an extensive trial of Mr. SANDWELL'S car will shortly be made.

THE Board of Trade has now completed and issued the "Model Order," which is to serve as a pattern for the Electric Lighting Companies of the Metropolis. At the time of writing it has not been long enough in our hands to admit of useful criticism.

THOSE of our readers who are concerned in Central Station Lighting projects will probably scarcely need to be reminded that by the Act of 1882 the time during which notice may be given to a local authority of intention to apply for a Provisional Order during the current year expires on July 1st.

WE learn that, in view of the pressure of work imposed upon the officials of the Telephone Companies owing to the amalgamation scheme now about to take effect, it has been decided to postpone the proposed Telephonic Convention until next year.

Ealing.—The renovated Maxim-Weston Company is taking steps to establish a central lighting station in the suburb of Ealing.

Foreign Import Duties.—The June number of *The Board of Trade Journal* contains a useful tabulated statement of the foreign import duties on dynamo-electric machinery and electric lamps.

Brazilian Order for Cable.—Rio advices, dated May 20, state that the Brazilian Government has ordered in London 5,500yds. of electric cable for the use of the torpedo factory belonging to the Navy department.

Electric Lighting Order Confirmation Bills.—The Bills for confirming the Board of Trade Provisional Orders for electric lighting at Birmingham, Liverpool and Swansea have now been issued as a Parliamentary Paper.

Telegraphic Cables in the Philippines.—The *Dia* states that the invitation for the construction of inter-insular cables in the Philippine Isles has been withdrawn, in the absence of any tender being sent in. It is stated that the conditions will be modified, and that tenders will be again invited.

Wire Samples.—We have received from the Telegraph Manufacturing Company of Helsby samples of fancy cotton covered wires, twin wires, and double silk covered flexible wires with various qualities of insulation. The whole are put into a very neat and convenient red cloth case, and are in appearance and size not unlike an ordinary guide-book.

Fireproof Insulation.—We have received from Mr. J. E. Hartley, of Birmingham, specimens of electric light wires covered with fireproof insulation; the coating appears to be treated with tungstate of soda or some similar compound. The use of such wires where there is the slightest danger of electric light wires communicating flame from one room to another in case of fire is highly to be recommended.

Chelsea.—The Chelsea Electricity Supply Company (Limited) have given the necessary statutory public notice that they have applied to the Board of Trade for a license for purposes set forth in their advertisement, and that all objections to the granting of such license must be lodged with the Board of Trade on or before the 8th August, 1889. This refers to the district assigned to this company by Major Marindin at the late Inquiry.

Official Telegraphic Messages in Brazil.—The cash receipts of the Brazilian Telegraphs for January are reported to have amounted to 68,056 milreis, while the official telegrams charged to the respective Government departments in the same month amounted to 61,191 milreis. Would it not be good policy, asks the *Rio News*, to cut down the official telegrams a little, and thus afford more facilities to private individuals who pay for the work done?

The Electric Sugar Swindle.—The New York correspondent of the *Daily News* says:—"William E. Howard, one of the leading spirits in the electric sugar-refining swindle, was found guilty yesterday of grand larceny of the first degree. The jury occupied only fifteen minutes in finding its verdict. Howard will be sentenced on Friday. The maximum punishmens is ten years' imprisonment. The other members of the company are to be tried as soon as possible.

The American Engineers at the Subway and at Deptford.—Under the guidance of Mr. J. H. Greathead, the engineer of the work, a large party of the American engineers visited the City and Southwark Subway on Wednesday morning. On the conclusion of their inspection they expressed high admiration of the work, and warmly complimented Mr. Greathead upon its execution. A second party of the American engineers visited the generating station of the London Electric Supply Corporation at Deptford.

Gillingham (Kent).—The local authorities at Gillingham, Kent, have received notification from the Gillingham Electric Light Supply Company of their intention to apply to the Board of Trade for a Provisional Order, to be confirmed in Parliament, giving them statutory powers to lay mains under the ground instead of overhead, and also for an authorisation to apply electricity for any private or public purposes within the district of Gillingham. The parochial authorities have decided not to oppose the application.

A "Long-Distance" Microphone.—Dr. Puluj has recently shown some interesting experiments at Prague with MM. Deckert and Homolka's microphone for long-distance telephony. The instrument consists of a round vibrating plate of carbon and of a thick carbon plate, into which notches are cut; between these two, little balls of platinised carbon are placed, which serve to conduct the current from one plate to the other. The results obtained are said to be better than those given by any microphone hitherto constructed.

The Lighting of the Strand District.—At the last meeting of the Strand Board of Works a letter was read from Messrs. Gatti, stating that they are able to supply electricity in the district to the extent of 8,000 lamps of 16 candle-power, and can extend it shortly to 30,000 lamps.—Mr. Laing said that he and Mr. Prescott, together with the Surveyor, attended before the Board of Trade and opposed the idea of any one company having a monopoly, which Mr. Courtenay Boyle endorsed. He would move that Messrs. Gatti have the same facilities as the Metropolitan.

Electric Motors at the Bank of England.—The Bank of England have decided to utilise their electrical plant for power purposes as well as lighting, and Messrs. Drake and Gorham have been instructed to erect one of their electric lifts for the conveyance of passengers and gold. Electric lifts are becoming somewhat general where electricity is available, and we understand that those which were erected at the London River Plate Bank, the English Bank of River Plate, the English Bank of

Digitized by Google

Rio de Janeiro, &c., have never given the slightest trouble or cost anything for repairs.

The Western and Brazilian Telegraph Company and the Government Tax.—By the contract with the Government, this company is expressly exempted from all taxes in Brazil, whether general, provincial, or municipal, but the agreement offers no obstacle to the tax collectors. For some time, says a Rio paper, the managers and agents of the company have been called upon to pay a tax for "exercising a profession," and the company having appealed, the Treasury has decided against the company. As the paper quoted justly remarks, "those who make contracts with the Brazilian Government should make a note of this."

The Cost of Lighting H.M.S. "Exmouth."—A report upon the subject of the electric lighting of the training-ship "Exmouth" has recently been presented. The report stated that the Managers were anxious to secure the best form of lighting, not only as regards economy, but also as regards safety. Three years had elapsed since the electric lighting of the ship had been completed, and the Managers had come to the conclusion that the approximate annual cost of such system was £665, while the annual average cost of lighting the ship by means of colza oil during a similar period was £680. A positive saving had thus been effected, besides obtaining a greater security from fire, together with other advantages, including the greater cleanliness and extended opportunity of training the boys in all parts of the ship, irrespective of atmospheric conditions, so that the actual cost of the electric light could only be regarded as approximate.

The Telephone in the West.—By means of a new trunk line of the Western Counties and South Wales Telephone Company, telephonic communication is now established between Torquay and Plymouth and intermediate places. The following are the rates charged for calls made by either subscribers or the general public between Plymouth and the various towns mentioned:—To Plympton, 4d.; to Ivybridge, Totnes, and Paignton, 6d. each; to Torquay, Dartmouth, Brixham, and Newton Abbot, 9d. each. The next telephonic extension contemplated will be to Yelverton, where, in response to several requests, the company hope to be able to open a small exchange, to the advantage of the large number of Plymouth people resident in that town. The Plymouth Exchange is now provided with a multiple switchboard; ladies on duty can answer any call without moving. The late superintendent (Mr. Anderson) has just been succeeded by Mr. C. V. O'Donnell, a gentleman of considerable experience in telephonic matters. Mr. O'Donnell began under the United Telephone Company in London, and then joined the Western Counties as Superintendent of the West Hants and Dorset District. Subsequently he acted as manager of the Sheffield, Lincoln, Chesterfield and Nottingham line of the National Telephone Company, and then, rejoining the Western, was appointed to Plymouth.

Engineering Society, King's College, London.—On Thursday last Mr. Charles Mittelhausen read his presidential address to the above Society on "A Few Recent Engineering Advances." The author showed experimentally how sewage could be precipitated electrically by means of iron electrodes on a small scale, and indicated how this long known scientific fact had been turned to practical account with the Webster process. In referring to the execution of criminals by electricity, it was pointed out that exhaustive experiments had now demonstrated the superiority of alternating currents for that purpose. The series system of electrical traction was then taken up, and by means of a model it was shown how the system had been made a complete success by the use of highly insulated conductors. Speaking on the advantages of photography for engineers, Grunston's new patent shutter was mentioned both on account of the simplicity and accessibility of its mechanism. The author also referred to Messrs. Siemens Brothers' new Morse instrument and Edison's new phonograph, whilst, *à propos* the question of national defence, the newest methods of operating submarine mines was explained. In the civil engineering world the chief features of the Forth and Lansdowne bridges were described, whilst the address terminated in an apology for the much maligned Eiffel Tower. After a vote of thanks to Mr. Mittelhausen for his interesting Paper, the meeting adjourned.

Search Lights at Malta.—A night attack on Valetta took place on the 11th ult. The "Benbow," "Phaeton," "Landrail," and "Don," with two first-class torpedo boats, left Malta harbour, says the *United Service Gazette*, about 3.30 p.m., and steamed away to the south-eastward. At 8 p.m. the batteries were manned and the electric search lights swept the surface of the water in all directions, but it was considerably later before the attacking squadron hove in sight. In the meantime, two merchant steamers making for the harbour were so surprised by the search lights on them, and by two guns fired at one of them under the impression that she was the "Landrail," that they turned seawards again, and waited until the operations were concluded. When the attacking force came near the harbour the batteries opened fire, and the ships replied, steaming along in front of the forts at about 1,500 yards distance. The second-class torpedo-boats made a dash at the "Phaeton," but were at once seen, and fire was opened on them. As a spectacle the attack was very fine, but there was too bright a moon for the search lights to be efficiently tested in discovering ships or boats. As, however, the principal object of the operations was to decide if the search lights on shore were placed in the most effective positions, the moonlight was not of so much consequence. It is stated that the military authorities do not consider their lights are placed as well as they might be, and alterations are to be made accordingly.

The School of Electrical Engineering and Submarine Telegraphy, Prince's-street, W.—Examinations for the certificate of this school have recently been conducted by Mr. Gisbert Kapp, A.I.C.E., and Mr. Kempe, of the Engineer-in-Chief's office, General Post Office. For the certificate in Electric Lighting and Power Transmission, Mr. Kapp set a Paper in mechanical and another in electrical engineering, and he devoted many hours to a practical and *vivâ voce* examination of the students on (to quote his report to the managers) "Steam boilers, steam engines, secondary batteries, dynamos, arc-lamps, calibrating, resistance measurements, jointing, photometry, switches, and management of circuits, and practical use of graphic methods as applied to dynamos." A minimum average of 70 per cent. of full marks in the practical work, and of 60 per cent. in each of the two Papers, is a necessary condition of obtaining the certificate. Of eleven students at the practical examination, only three failed to exceed this minimum. Certificates in Electric Lighting and Power have accordingly been awarded, on Mr. Kapp's report, to the following gentlemen:—Messrs. Wm. J. Alexander, G. Horley, Th. Raaschon, F. Wallis. Mr. H. R. Kempe set two Papers, one upon Electrical Testing generally, and the second containing special and practical questions upon Telegraphy and Telephony, in which a minimum of 70 per cent. of full marks was required. As the result of his report, certificates in these subjects have been awarded to Messrs. Wm. St. J. Beale, H. C. Moberly, H. H. Paynter.

A "Fault" in an Ocean Cable.—The value of laying ocean cables containing two cores was shown, says the *Electrical World* (New York), during the violent storm of Nov. 25, 1888, when a fishing schooner, about 26 miles from Gloucester, Mass., dragged her anchor for some distance, until at last she hooked the Rockport cable of the Commercial Cable Company's system, riding to it for about 48 hours. It was found, when picking up the cable during the repair, that she had dragged along it for some 400 yards, tearing off the outer covering of jute and compound, also one of the armour wires, rolling it up into a tangled mass, and at last driving the end of the steel armour wire between the sheathing of the cable and through one of the cores, but leaving the other absolutely intact. With a single-core cable of the ordinary type communication would have been interrupted until repairs were effected; but in this case, by means of the uninjured core, traffic was passing continuously with the exception of a few hours, during which the repair steamer had the cable cut in order to remove the fault. Considering the extreme violence of the gale and the large size of the vessel, it is surprising that the cable did not part, and the incident speaks well for the mechanical strength of the cable. The repair was made by the steamship "Pouyer-Quertier," which was chartered for the purpose, as she was the only available cable steamer on this side of the Atlantic. Captain S. Fossard, who commanded the

Digitized by Google

steamer, showed such great skill in manœuvring her, that although 2½ miles of cable was picked up and relaid across a tideway of four knots per hour, it was found, on completion of the repair, that the cable was only lengthened by a few yards. The electrical department on board was in charge of Mr. Charles Cuttriss, the company's electrician. This remarkable "fault" has now been placed on exhibition at the Paris Exposition by the Commercial Cable Company.

Leeds.—A meeting of the Electric Lighting Committee of the Leeds Corporation was held last week to consider the report of the Borough Engineer in reference to electric lighting in Leeds. The report was considered at great length, and it was agreed to adopt the recommendations it contained in reference to the lighting by electricity of the Council Chamber, the Courts of Justice, and the offices in the Town Hall and the Municipal Buildings. The proposal as to the establishment of a central electric station upon the "Midden" was deferred to a future meeting. It is proposed that the arc lamps shall be fixed in the streets surrounding the Town Hall. It is estimated that over 2,000 lamps will be required to illuminate the Town Hall and Municipal Buildings, and that the scheme will cost £3,000. At a subsequent meeting of the Electric Lighting Committee, held on Wednesday last, the Committee proceeded to discuss the terms of the report in detail. In the end it was resolved, on the motion of Alderman Tatham, seconded by Alderman Spark, "That the Council be recommended to carry out the electric light in and about the Town Hall and Municipal Buildings, as referred to in the report, at an estimated expenditure of £3,000." Further, it was decided to ask the Corporation to make application to the Board of Trade for a Provisional Order, authorising them to apply electricity to public and private lighting purposes within an area described in the report, at an estimated expenditure of £68,000. It was explained that the area alluded to comprises not only the central, but also the residential districts of the town A third recommendation is to the effect that when the Provisional Order has been obtained, the Council shall grant to the Committee the sum of £25,000, which represents the estimated outlay upon an initial installation of the electric light within a district set out in the report. It was mentioned that the £25,000 will form part of the suggested outlay of £68,000, and that for the former sum probably all within the prescribed area who wanted the light might be furnished with it, after which the plant might be added to as the demand for the new system of illumination increased.

Thunderstorms and Lightning.—At the meeting of the Royal Meteorological Society, held on Wednesday evening last, Mr. W. Marriott gave a graphic and interesting account of the recent thunderstorms which have prevailed over this country. On Sunday, June 2nd, a thunderstorm passed across the country in a northerly direction from Wiltshire about 3 a.m., and reaching Edinburgh by 10.44. It travelled at the rate of about 50 miles an hour. It is possible that this storm travelled still further north, and reached Kirkwall at 3.37 p.m. A severe thunderstorm prevailed over the neighbourhood of the Tweed between 11 a.m. and noon, and was accompanied by hail of very large size, some of the stones being 5in. in circumference. A very destructive storm occurred over the whole of the north-west of England and south of Scotland during the afternoon; much damage was caused by lightning, and very large hail fell over a large area. Some of the hailstones measured 7in. in circumference, and weighed 7oz. During the night of the same day a severe thunderstorm prevailed over Norfolk, which was also accompanied by very large hailstones, some of which were 5 to 6in. in circumference. On Thursday, the 6th, thunderstorms prevailed during the afternoon over the whole of the south-east of England. That which passed over the metropolis about nine o'clock was remarkable for the brilliant and continuous display of lightning. During the night and in the early morning of the following day a very destructive storm prevailed over the Eastern Counties, much damage being done by the lightning in the north-west of Norfolk. Several hailstorms occurred between two and three o'clock at Margate and Ipswich. During the afternoon of this day destructive thunderstorms prevailed over the whole of the Southern Counties, much damage being done by lightning, while at Tunbridge Wells there was a most remarkable hailstorm. One of the hailstones which was weighed was actually half a pound in weight. An interesting collection of over 40 photographs of lightning, taken during the storm on June 6th, was also exhibited to the meeting. In addition to the sinuous, ribbon, and meandering flashes of lightning, several photographs showed knotted, multiple, and dark flashes.

The Proposed Electrical and Engineering Exhibition in Edinburgh.—On the 13th inst., a deputation representing a large and influential committee of citizens waited upon the Lord Provost of Edinburgh, for the purpose of placing before his lordship a scheme which has been inaugurated for holding during the spring of next year an Electrical and Mechanical Engineering and Inventions Exhibition in Edinburgh, and to which we referred as being in process of incubation some weeks ago. There were present:—Bailie Walcot, Principal Grant Ogilvie Messrs. A. R. Bennett, National Telephone Company; David Allan Stevenson, C.E.; J. W. W. Barclay, Mitchell Thomson, Geo. E. Watson, C.A., interim secretary; J. Harrison, &c. Mr. Bennett explained to the Lord Provost that it was proposed to celebrate the opening of the Forth Bridge by holding such an Exhibition on a large scale, and one which would interest all classes of the community throughout Scotland. The Exhibition would probably be open for several months; and its attractions, from the fact that the greatest electrical engineers and inventors would be represented, would be undoubted. It was mentioned that the deputation represented a large committee, among whom were Profs. Tait, Armstrong, Crum Brown, and Chrystal, the Lord Justice-Clerk, and many others.—The Lord-Provost (whose patronage and that of the Council the deputation desired) said that he would give the matter his most favourable consideration, and, speaking in approving terms of the project, he said he would be glad to see the deputation before the Corporation on the following Tuesday at their meeting. At the meeting of the Edinburgh Town Council, held on Wednesday, the Council unanimously agreed to receive a deputation of citizens with reference to the proposed Exhibition. On the introduction of the deputation, Mr. A. R. Bennett drew attention to the backward state of Scotland with regard to electrical science, especially when compared with the United States of America, where electricity was applied to a multiplicity of objects, and entered into the everyday life of the citizens of even the smaller towns of the United States to such an extent that he had no hesitation in saying that the street Arabs in a Western town were more conversant with the present applications of electricity than many educated men among themselves. In order to illustrate the growth in the application of electricity, he said the Board of Trade returns showed that during the first three months of 1888 the exports of electrical apparatus from Great Britain amounted to £88,077, while for the corresponding period this year they were valued at £430,309, nearly five times as much, and bordering closely upon half a million pounds. He would ask what was Scotland's share of this amount? He was afraid it was very little indeed, for they could count on the fingers of one hand the number of manufacturing firms in Scotland. Notwithstanding the rate of progress of electricity — 185,000 miles a second — it had not travelled far into Scotland. The Exhibition would, he believed, show to the people in the North, who were badly supplied with the means of communication with other places, and owing to their distance from the coal fields had an indifferent supply of fuel, that they had in their great rivers — such as the Ness, Spey, and Tay — a wealth inferior only to the mines of Golconda. Prof. Armstrong expressed his entire sympathy with the project. They believed the project was good in itself—good commercially—and that it would be a benefit to this ancient city, and to the advancement of science. It would partake in a large degree of the character of an International Exhibition, inasmuch as many of the most astonishing practical developments of electricity came from the other side of the Atlantic or the Continent, and they would have concentrated in Edinburgh all that was best and most advanced in respect of the application of electricity and mechanical invention generally. The Lord Provost said they would carefully consider the subject. The subject was then remitted to the Lord Provost's committee.

LIGHTNING CONDUCTORS.—VIII.

BY DR. OLIVER LODGE.

(Continued from page 246, Vol. XXII.)

Alternative Paths Experiments—*(Continued).*

There has been rather a long break in the appearance of these Papers, due mainly to other work, and I am rather tempted to interpolate here an account of "recoil-kick" experiments, because these are the experiments which prove the velocity of a pulse along a pair of isolated wires to be very closely indeed the velocity of light—a matter of some interest at the present time, because Hertz has, by his interference experiment, been led to a different conclusion, and asserts that waves go at a different speed along wires and through air. This being so, there is a difference between us, and the account of my experiments supporting the theory of Maxwell and Heaviside shall be proceeded with directly the record of alternative path experiment is concluded. I go on now from p. 246, Jan. 4.

Experiments in September, 1887.

46. The arrangement depicted in Fig. 9 was still employed; but a couple of pint jars were substituted for the two small Voss jars. The static capacity was by this change raised from 143 centimetres to 670 centimetres, or nearly fivefold. The A spark was 1·35 centimetres long between the knobs of the immersed discharges (or reduced to flat plates, 1·1 centimetres). It could be placed in either of the three positions shown in the figure, and its light was always screened off the B knobs. These were adjusted till the B spark between them was just failing, passing occasionally, but missing much more often. The alternative

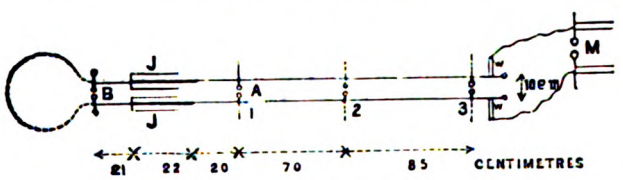

FIG. 9.

paths used were wire circles, about 2ft. in diameter, whose particulars are already recorded in Section 42. The following are the results:—

Pint Jars.

Alternative path.	Length of B spark for different positions of A, in millimetres.		
	Position 1.	Position 2.	Position 3.
None	6·50	7·35	8·50
No. 25 iron	5·8	4·7	3·65
No. 2 iron	5·0	—	2·0
No. 5 copper	5·0	—	2·0
No. 23 copper	5·85	—	2·5
No. 40 copper	6·3	—	4·5
No. 2½ brass	5·3	—	2·15
No. 24 brass	5·9	—	3·55

The pair of wires called "longer leads" were now inserted between the discharger and the jars, and the A spark had to be shortened to 7·5 millimetres. The following were now the readings of the B spark:—

Alternative path.	B spark in millimetres.	Alternative path.	B spark in millimetres.
None	10·55	No. 23 copper ...	·44
No. 5 copper	·22	No. 25 iron	·45
No. 2 iron	·25	No. 40 copper ...	·86

47. Applying theory to these experimental results, we deduce the following values for the rate of alternation per second, and for the maximum strength of current passing through the conductors.

The rate of alternation is slightly different for the different alternative paths. The extreme values are those for the thickest iron and the thinnest copper; so, taking them as examples, we have—

Pint Jars.

Thickest Wires.

Position of A knobs.	Rate of alternation.	Strength of max. current.	Impedance of alternative path.
No. 1	3·1 millions per sec.	3,000 amperes	7 ohms
No. 3	2·2 millions per sec.	2,500 amperes	5 ohms
End of longer leads	0·52 millions per sec.	[670 amperes]	1·2 ohms

Thinnest Wires.

No. 1	2·4 millions per sec.	2,700 amperes	10 ohms
No. 3	2·0 millions per sec.	2,500 amperes	8·5 ohms
End of longer leads	0·52 million per sec.	[660 amperes]	2·2 ohms

The strength of current put in square brackets in the third column is what corresponds to the same A spark length as in the other two columns. In actual fact this spark length had to be reduced because of leakage, and accordingly the current was reduced too in about the same proportion.

With the Voss jars the rate of alternation will be rather more than double and the current amplitude about half what is recorded for the two pint jars.

Comparison between Theory and Experiment.

48. Calculating absolutely to the length of B spark theoretically to be expected, by means of the first approximation, which ought to serve for this case, I do not find a good agreement when small jars are used, the Voss jars giving greater disagreement than the pint jars. The sparks observed are shorter than $\frac{L_0}{L+L_0}$ times the A spark. I am not prepared to say why this is, unless it be that loss by radiation damps out the vibration with these small capacities more quickly than one might suppose.

But it may be worth noticing that, taking merely relative numbers, the agreement is very fair. Thus, if we multiply the value $\frac{L_0}{L+L_0}$ by the factor 7·6 (instead of by 11, the length of the A spark between flat plates in millimetres), we get the column called "calculated (relative)" in the annexed table.

Pint Jars.

Alternative path, and position of A.	Calculated (Relative).	Observed.
No. 25 iron ... Position 1	5·9	5·8
No. 25 iron ... Position 2	4·6	4·7
No. 25 iron ... Position 3	3·6	3·7
No. 2 iron ... Position 1	5·1	5·0
No. 2 iron ... Position 3	2·7	2·0
No. 5 copper Position 1	5·2	5·0
No. 5 copper Position 3	2·8	2·0
No. 23 copper Position 1	5·8	5·0
No. 23 copper Position 3	3·5	2·5
No. 40 copper Position 1	6·2	6·3
No. 40 copper Position 3	3·9	4·5
No. 2½ brass ... Position 1	5·2	5·3
No. 2½ brass ... Position 3	2·8	2·2
No. 24 brass ... Position 1	5·9	5·9
No. 24 brass ... Position 3	3·5	3·6

The agreement here is not perfect, but it is not very bad.

49. When the longer leads are inserted, with a self-induction of about 1,000 metres, the same mode of calculation gives us the theoretical spark lengths for B as closely proportional to the self-induction of the alternate paths, but it is improbable that the first approximation is now sufficient, especially with the No. 40 wire. It is scarcely worth troubling about the second approximate in such a case as this, so I will proceed with the record of experiment, using the gallon jars instead of the pint.

Digitized by Google

The A spark is still 1·35, and everything remains the same as before, the light being screened off.

The capacity charged is now 2,890 centimetres, except when the long leads are used, and then it is 3,040.

Gallon Jars.

Alternative path.	B spark length when half sparks fail, for different position of A.		
	A_1.	A_2.	A_3.
None	8·2	—	9·1

Comparison with Theory.

51. Taking the ratio $\frac{L_0}{L+L_0}$ and multiplying it by the length of the A spark, we get very fair accord between theory and experiment. But the agreement is still closer if instead of multiplying by 11 we multiply by an arbitrary factor 10 for the longer A spark and by 7·1 for the shortened one. The following table shows the comparison between calculation and observation for the longer A spark :—

Gallon Jars.

——		$\left\{\frac{10\,L_0}{L+L_0}\right\}$ Calculated (relative).	Observed B spark.
No. 25 iron	1	7·2	7·1

Historical Note.

53. It has been everybody's opinion, I believe, that the original alternative-path experiment was performed by Faraday ; but Mr. Oliver Heaviside has been good enough to send me the enclosed extract showing that it is much older and is due to Priestley :—

Extract from John Cuthbertson's "Practical Electricity and Galvanism," dated 1807. Printed for J. Callow, London.

"An electric discharge prefers a short passage through the air to a long one through good conductors.

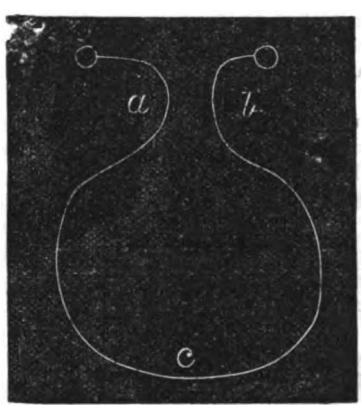

Fig 57

'Exp. 106.—Bend a wire, about 5ft. long, in the form represented by Fig. 57, that the parts *a b* may stand about a quarter of an inch from each other, then connect the end *a* to the outside of a battery or coated surface sufficient to melt wire. When it is charged set one leg of the insulated discharge upon *a* and make the other end to touch one of the knobs of the battery : it will be discharged. At the time of the explosion a spark will be seen between *a* and *b*, which shows that the electric fluid prefers a short passage through the air to a long one through the wire. This spark at first was supposed to contain the whole discharge, but the contrary is proved by the following experiment :

"Exp. 107.—Lay a small wire from *a* to *b* of such a thickness as the battery is capable of melting when charged to the same height as before ; discharge it, and the small wire will not be melted ; cut the large wire in two at *c* so as to disconnect the circuit, make a discharge as before, and the small wire will be melted by the same explosion which before scarcely made it red hot. In this manner Dr. Priestley, who is the inventor of this experiment, states the conducting power of different metals may be tried, using metallic circuits of the same length and thickness, and noting passage through the air in each case.

THE PARIS EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT).

June 14, 1889.

From an electrical point of view the English section is very disappointing, the only firm exhibiting on anything like an extensive scale being Messrs. Crompton and Co., Chelmsford. The appearance of their stand, which measures 22ft. by 20ft., is somewhat spoilt from want of space; this is due to the fact that it was originally intended to drive the dynamo machines by coupling them direct to Willans' engines, but the recent fire at Thames Ditton prevented Messrs. Willans and Robinson completing the work in time, and at the last moment Westinghouse engines, from Scotland, had to be substituted.

There are three Westinghouse engines, each capable of developing 100 horse-power at a speed of 300 revolutions per minute; they are supplied with steam from the boilers at the station of the Exhibition Electric Lighting Syndicate, which is outside the Palais des Machines, and necessitates the steam being brought through 600ft. of 6in. piping, laid underground, and covered with the "United" asbestos composition. The pipes have a fall of one in twenty, ending in a separator and trap of Macdonal manufacture.

The Westinghouse engines are coupled to six dynamo machines by means of ordinary belting, working between 10ft. and 7ft. 6in. centres. One engine drives two low-tension machines, whilst each of the other engines drives one low and one high-tension machine.

Four dynamos only are required for the actual work being done, so that two machines and one engine are kept in reserve in case of breakdown.

The high-tension machines run twenty-four 25-ampere arc lamps of 5,000 candle-power each in series; these light the whole of the British and United States section as well as part of the French. The lamps are of a special pattern designed expressly for the Exhibition. The raising and lowering gear is similar to that employed at the Mansion House lighting some few years ago, consisting of a double pulley-block and fall arrangement counterpoised, working with Messrs. Walter T. Glover and Co.'s flexible conductors with 98/26 B.W.G. copper core. In consequence of this arrangement, Messrs. Crompton's lamps present by far the best appearance of any in this hall, as they are always hung at precisely the same height, and are not made unsightly by slack wires. It is not improbable that some other exhibitors will adopt the same method of suspension.

Owing to the great height from the ground, namely, 15 metres, at which these lamps are hung, Mr. Chamin, the engineer, has experienced very great difficulty in getting them down for trimming, as the existence of a travelling crane necessitates the lowering cord being 12 metres from the ground. From the end of the cord below the lamp is hung a ring 18in. diameter. Through this Mr. Chamin (who must be an expert toxophilist) shoots an arrow to which is attached a string, thus dispensing with a high step ladder that used to take three men to move it.

In addition to lighting the main hall, Messrs. Crompton have seventy-nine small arc lamps of 500 candle-power each in the upper gallery.

These are arranged in seventeen parallels of series of three, and in each series there is also placed a resistance. In the last series, where there is but one lamp, a correspondingly greater resistance is of course placed. The dynamo machine running this group of lamps gives an E.M.F. of 220 volts.

At the foot of the staircase, near the Avenue de la Bourdonnais, there are four iron standards to hold forty 16 candle-power lamps each. From the low-tension circuit there is being run a motor which drives one of Messrs. Avery and Co.'s cartridge-filling machines; it is believed that this is but one of many motors that will ultimately be seen running in the British and United States sections.

Blackpool Tramway.—We learn that on Whit-Monday over 11,000 passengers were carried by the Blackpool Electric Tramway, and the receipts amounted to more than £87.

REVIEWS.

Papers on Alternating Currents of Electricity. By T. H. BLAKESLEY, M.A. Second Edition. Specialists' series. (Whittaker and Co., London.)

We are glad to welcome a new edition of Mr. Blakesley's little book on "Alternating Currents of Electricity." Our readers will recollect that these Papers originally appeared in the columns of *The Electrician*, and afterwards were published in a separate form. The present edition will be found to embody some modifications and additions. At a time when two large and powerful corporations are making their preparations to provide electric illumination for a considerable area of the metropolis by means of alternating currents, it is certainly necessary that electrical engineers should have all the help they can obtain to assist them to master the vagaries of all sorts and conditions of periodic currents, and to grapple with the problems presented in their ordinary and extraordinary behaviour. The chief aim of the author of this book has been to exemplify the use of geometrical methods of dealing with these problems, on the assumption that the periodic character can be represented by a simple sine curve. It has sometimes been said that investigations of this kind have a purely theoretical interest, because practical periodic currents are not, or may not be generally, truly harmonic, and hence the electrical student is not much more helped by them than the student of mechanics is by mechanical text-books which treat of perfectly rigid levers, perfectly flexible cords and frictionless pulleys. The reply, however, is that in elementary teaching some completeness of treatment must at first be sacrificed for the sake of clearness; and next, that since all periodic currents of any kind are the result of superposition of simple periodic currents, an approximation to a first degree is still even in practice very useful; and lastly, that the not quite perfect theory may yet be a very useful guide in actual practice and be subsequently modified by experience to closer agreement with facts. Mr. Blakesley's book is divided into thirteen chapters. The first, which is headed Self-Induction, deals chiefly with the addition of simple periodic electro-motive forces when represented graphically by straight lines, the length of which is proportional to their maximum value, and whose simultaneous projection on any line gives their values at any instant. Mr. Blakesley's formulæ would be much simplified by letting the symbol T stand for the *complete* periodic time, by selecting some single symbol to denote $\frac{2\pi}{T}$, and finally by adopting the now frequently used term impedance for the oft-recurring expression $\sqrt{r^2+\frac{4\pi^2}{T^2}L^2}$. Long and unsymmetical formulæ like those on page 20 for the values of the primary and secondary current strengths in the case of two mutually inducing coils are thereby rendered much more expressive. In the second chapter on Mutual Induction Mr. Blakesley apparently objects to Mr. Willoughby Smith's use of the idea of magnetic screening in his experiments on metallic plates inserted between two inducing coils, and seems to imply that the effect of inserting such a screen is always to reduce the mean strength of the primary current. He quotes an experiment of his own with an induction coil having a telephone in its secondary circuit and a tuning-fork interrupter in its primary, and states that the insertion of the core (presumably iron) reduced the intensity of tone given by the tuning-fork, the inference being that the primary current was reduced in strength. This is quite in accordance with theory. The impedance of the primary circuit is increased by the insertion of the iron core; but Mr. Blakesley would have found a different result if he had used instead a solid copper core. Magnetic screening is an undoubted fact, and although objection may be taken to the interpretation put by Mr. Willoughby Smith on some of his results, the final reasons for belief in it rest on far broader foundations.

In Chapter III. we are brought to the subject of condensers charged by periodic currents, and the simple theory of the relation of charging current and potential difference is given. In Chapters IV. and V. the theory of condensers shunted by non-inductive shunts is established, and as a consequence we are

Digitized by Google

introduced to the flow of periodic current in circuits having capacity. It would have been well first to have pointed out broadly to the student that a perfectly insulating condenser acts towards a periodic electro-motive force impressed on its terminals as if it were a non-dissipative conductor having a negative self-induction. In other words, it passes a certain quantity of electricity per second, but in the absence of true conduction or leakage there is no dissipation of energy involved. A circuit having self-induction resists the formation of a current in it, and when it is formed tends to propagate it in the same direction on the withdrawal of the force. A condenser acts in an opposite manner, and discharges its energy as a current in a direction against the impressed electro-motive force when this latter is removed. Accordingly the action of the condenser placed as a shunt across a portion of an inductionless series of incandescence lamp, is obviously (*see* p. 41) that of a conductor. It robs the further section of current and makes those lamps duller, while the lamps in the section near to the generator carry additional current for the condenser and are rendered brighter. Chapter VI. introduces us to the same subject considered when self-induction in the shunts and leads is involved. The practical case of a condenser and self-inductive circuit joined in series is treated, and it is shown that for a particular relation of periodicity, capacity, and inductance the coil and condenser in series permit a current to pass just as if the combination were a simple resistance without self-induction; in other words, the condenser placed in series with the coil annuls its self-induction. In Chapter VII. condenser transformers are explained. When a condenser is joined up to the ends of a non-inductive resistance the current in the resistance is always *less* than it would be if the condenser is removed, but if the resistance has self-induction then the current may be *greater*. This is equivalent to saying that the condenser annuls in part the self-induction of the coil. In high-speed telegraphy it has been found possible to greatly quicken the response of a relay by short-circuiting it with a condenser, the explanation being that the self-induction of the electro-magnet is partly annulled by the condenser.

The two following chapters deal with the flow of periodic currents in a circuit having capacity, say a submarine cable, and as a natural result involve a discussion of the problem of long-distance telephony. Mr. Blakesley puts very clearly what are the causes and conditions limiting long-distance telephony. The various simple tones which go to build up every complex sound are variously degraded in strength, and hence it arrives at the other end no longer having the same wave form. If every proportion of a face or figure is reduced in the same ratio we obtain a recognisable miniature or portrait, but if the sizes of component lines are variously reduced we get a *caricature*. The effect of electric capacity in a telephonic cable on a composite wave of current is similarly to change or burlesque the wave form, and hence render it impossible for the ear at the receiver to guess the original form when it has been disguised by this change beyond a certain amount. Chapter X. presents us with the problem of transmission of power by alternating currents. We think this chapter would have been more generally useful if it had dealt briefly with the practical experiments which have been made on that point. The general problem of the transmission of power by alternating currents is bound up with that of driving alternators in parallel circuit. It is now well known that separately driven alternators will in general "cophasedly synchronise" one another when put in parallel on the same circuit. All real alternators will not, however, do this equally well. Mr. Blakesley brings to bear his geometrical method to show—as had been done previously by Dr. Hopkinson, using analytical methods—that if under these circumstances one machine lags in phase behind its fellow, its work will be decreased, and it will be brought into phase again. The important question which, however, requires elucidation is the examination of the circumstances which contribute to produce the maximum stability. For practical success it is necessary that the smallest lag of one machine behind the other should be checked immediately; in other words, the least attempt to get out of step should bring into existence very considerable forces of restitution, and the equilibrium of cophasial synchronisation should be not only stable but hard to displace.

In the light of recent discussions on the question of the bearing of high or low armature self-induction or great or small periodicity on this mutual control of machines there can be no doubt that Mr. Blakesley will in another edition find further points to discuss before the problems can be considered exhausted. Chapter XI. contains a very useful and very practical discussion of the employment of the two-coil dynamometer to measure the phase difference of periodic currents and to measure self and mutual induction coefficients when simple periodic currents of known periodicity are available. These methods have been largely borrowed by Prof. Ferraris in investigations on transformers.

The final chapter discusses magnetic lag. There are two notions which are sometimes mixed up in using this phrase, which ought really to be kept separate. When an extremely small particle of soft iron is subjected to the sudden application of magnetising force, it may be that a small interval of time elapses before it reaches the state of magnetisation appropriate to this force. This delay, if it can be detected, is properly called magnetic lag. On the other hand, when an iron bar of finite size is subjected to external magnetising force, owing to the gradual evanescence of the surface eddy currents, which exert a reverse magnetising force, there is a delay in time occupied in propagating through the mass the magnetising force. As far as observation goes the result is the same, whether the delay in the appearance of full magnetisation is due to growth of magnetisation or growth of magnetising force. Mr. Blakesley's ingenious method with the three dynamometers really measures the lag of magnetic induction or magnetisation behind magnetising force, no matter what may be the ultimate nature of the cause. No subdivision of the iron gets rid entirely of eddy currents. Mr. Blakesley gives the result of one practical experiment, in which he found that the magnetisation in a small transformer core lagged 5deg. or 6deg. behind the magnetising force. Prof. Ferraris found that with solid iron cores the lag might be as much as 45deg. Mr. Blakesley's conclusion that whatever causes magnetic lag is also a cause of dissipation of energy in the core is undoubtedly a correct conclusion. On the whole, we can recommend this short treatise as a useful addition to the library of an electrician. It is written with great clearness and compactness of statement, and well maintains the character of the series of books with which it is now issued.

Days with Industrials. By A. H. Japp, LL.D., F.R.S. (London: Trübner and Co.)

This is a collection of essays relating to some of those curious industries about which little has been written except in encyclopædic form, including the cultivation of quinine, the boring for petroleum, the manufacture of artificial diamonds, and the like. There is a short article entitled "The Electric Telegraph," more than half of which is taken up with the pneumatic system of transmission, probably for the sufficient reason that the author knows nothing of telegraphy, as is evidenced by his describing the Wheatstone transmitter as being "turned by a handle."

Electric Light for the Million. By Arthur Frederick Guy. (London: Simpkin, Marshall and Co)

This little pamphlet announces itself as a handbook for the uninitiated, of practical information on electric lighting and its cost. In the short space of 31 pages the author deals with the progress and advantages of the electric light, its production, the various systems employed, the approximate cost of installing plant where a central-station service does not happen to be available, and concludes with practical hints and general remarks.

Although the subject is necessarily and indeed intentionally treated in the most superficial manner, yet the pamphlet should serve a useful purpose in showing those who are still prejudiced against the adoption of electricity how practicable it has become, and that it is no longer the expensive and erratic agency it was but comparatively few years back. We may add that the author understands his subject—a fact which painful experience teaches us is by no means to be taken for granted in books on electricity addressed to the million—and, moreover, his estimates may safely be taken as a fairly trustworthy guide to the probable expenditure.

ELECTRICAL STANDARDISING LABORATORY.

DEPUTATION TO THE PRESIDENT OF THE BOARD OF TRADE.

On Wednesday a joint deputation from the London Chamber of Commerce and the Institution of Electrical Engineers had an interview with Sir Michael Hicks-Beach at the offices of the Board of Trade, to urge the Government to establish an Electrical Standardising Laboratory. The President was accompanied by Lord Balfour of Burleigh, Mr. Calcraft, Mr. Courtenay Boyle, Sir Thomas Blomfield, Major Marindin, and Major Carden, officials of the Board. The deputation consisted of Sir William Thomson (President of the Institution of Electrical Engineers), Lord Rayleigh, Sir Douglas Galton, Sir Vincent Barrington, Professors Geo. Forbes, Silvanus Thompson, Perry, Hughes, Adams, Powey, and Foster, Major Flood Page, General Webber, and Messrs. Crompton, Fleming, Lant Carpenter, Trotter, Kapp, Swinburne, Latimer Clark, Gaycke, F. B. Led, and Mr. Webb, secretary of the Institution of Electrical Engineers.

LORD RAYLEIGH introduced the deputation. He said they represented two bodies, the Electrical Section of the London Chamber of Commerce and the Institution of Electrical Engineers. The London Chamber had deputed three gentlemen to represent them—Lord Crawford and Balcarres, Sir John Lubbock, and Sir Vincent Barrington. Sir John Lubbock was abroad, and Lord Crawford was detained at Deptford, entertaining a party of American electricians, but he had written the following letter :—

"I am very sorry that I am unable to be present at the deputation to the President of the Board of Trade, as I have to receive a large number of American engineers who are visiting Deptford.

"Had I been able to speak to-morrow I had intended to have drawn attention mainly to the requirements of undertakers as affected by the clauses of the Provisional Orders, and to show that obligations are put upon them to supply all descriptions of instruments for measuring quantity or pressure of an electric current. That for which there is the greatest demand is the meter. Every consumer has a right to clean a meter which must be a 'certified meter,' *i.e.*, that it must have been compared with a standard and stamped as correct. An *uncertificated* meter will be of no *legal* use to us, as its readings cannot be taken as evidence. So much for quantity.

"Pressure has to be measured also, and we may be called upon to supply voltmeters.

"There are presently existing good and reliable forms of this instrument, but owing to the want of reliable standards, instruments are often found to vary as much as 8 to 10 per cent. *inter se*. Clause 47 (1) contemplates another form of meter, *i.e.*, an energy meter (watt-meter), which would be otherwise obtained by combining the results of the foregoing instruments.

"Up to this time not one of these instruments can be supplied to customers so as to comply with the clauses of the Order, and if I were to send in to the Department a batch of 100 meters for certification, there is no existing means at its disposal to enable us to conform to regulation. We hold, therefore, that the Department should without delay inaugurate a laboratory where we may send in our instruments to be passed in a manner similar to the procedure in the Weights and Measures Act. I think there is but little doubt but that such an establishment would very shortly pay its way, and would not be a burden on Her Majesty's Treasury. I consider that the average number of lights at the present time would be found to be about 30 per consumer; we are now putting up plant for the supply of 250,000 lights, which, according to the above-mentioned rate, would require some 8,000 meters (Coulomb meters). We shall soon lay down another station for about 250,000 lights, and this will involve more meters. These figures may practically be doubled, as there is one other undertaker who will certainly require an equal number of meters to be certified. Large numbers will also be required for the provinces. A small fee for certificates would suffice to pay the expenses of such a laboratory, as in addition to large numbers of new instruments, every time that an old one is interfered with for cleaning, &c., it will have again to be certified. There are many other important matters, but they are in able hands, so that I may well leave it with them.—Very faithfully yours, CRAWFORD."

LORD RAYLEIGH continued: The point to which Lord Crawford had there directed attention was the main object of the deputation. The time had arrived in which there was a certainty of an electrical supply on a large scale. That supply could not be afforded in accordance with the terms of existing legislation without the use of certified instruments, and at the present time there was no means of getting such certifications. There were many more competent to speak on this question and the importance of such an institution. His own experience had been principally on the scientific side. Ten years ago those electrical standards were in a rather uncertain position. There were 2 or 3 per cent. difference as to what the standards actually were, but that was a thing now of the past, owing to the labours of a good many men. The principal standards of resistance and current were not now uncertain, so that there was no difficulty in the issuing of certificates stating what the actual value of the instrument was. During the last few years a great deal of ingenuity had been displayed upon the invention of meters of various kinds, and these were now considered to be satisfactory. They might admit of improvement in the future, but the time had come when the Board of Trade should issue certificates, so as to put electrical measuring instruments in the same position as weights for ordinary measures now stood. The whole matter lay in a very small compass. Electrical engineers were to issue certificated standards, and there was at present no means of obeying the law

Sir WM. THOMSON then read the points which had been agreed upon to be submitted to the Board of Trade as follows :—

1. That it is impossible that the supply of electrical energy under statutory powers can be efficiently carried out without the provision of some means of standardising the meters and other instruments used in connection with such supply.
2. That the Board of Trade has recognised the necessity for this by inserting in Licenses and Provisional Orders clauses requiring that these meters, &c., shall be of a pattern approved by the Board of Trade as certified as correct by a properly-appointed inspector.
3. That the ordinary trade in electrical machines and instruments is much hampered and rendered uncertain by the want of generally recognised standards of electrical quantities.
4. That the required standards should be maintained by the Board of Trade as the department of Government entrusted with the administration of the Electric Lighting Acts, and as the warden of the standards of quantities used in other trades.
5. That being strongly impressed with the absolute necessity for the establishment of a standardising laboratory, where measurements of the various electrical quantities could be effected with the requisite precision, and whence certificates would be issued which would be accepted generally, the electrical section of the London Chamber of Commerce approached the Council of the Institution of Electrical Engineers on the subject.
6. That in consequence a joint committee of the two bodies was appointed to consider the matter, and that this committee has arrived at the following conclusions :—
   (*a*) That the absolute value of the accepted units of the various electrical quantities has now been determined with such accuracy that the possible error cannot exceed $\frac{1}{4}\frac{1}{0}\frac{1}{0}$, or one-quarter per cent. The most recent determinations may therefore be taken, for practical purposes, as correct, and no future corrections vitiating previous certificates need be apprehended.
   (*b*) That instruments and methods are now available by means of which the constancy and accuracy of measurement of electrical units and multiples of these units in a properly-equipped laboratory and under proper supervision can be assured.
   (*c*) That the cost of establishment of such a laboratory, exclusive of building, on the smallest scale suitable for the present requirements of the trade will not exceed the sum of £4,000.
   (*d*) That the joint committee aforesaid has devoted much time and consideration to the question and the estimate at which they have arrived is as close as it was possible to make.
   (*e*) That they further are of opinion that by charging moderate fees for comparisons and certificates, the Board of Trade would be in a position to remit the Treasury interest on this outlay, and also to provide fund for maintenance and possible extension of the laboratory.
7. That we have now the honour to bring the above-mentioned facts to your notice, and pray that they may receive the serious consideration of the Board of Trade.

He might say, from a scientific point of view, that the possibility of electrical measurement in the manner put before the President had become demonstrated within the last few years very much, he must say, from the labours of Lord Rayleigh. Through his labours the correct determination of the standard of resistance had been made. At the Paris Congress in 1881, the measurements of Lord Rayleigh in this country and of experimentisers from all parts of Europe were collated, and the present standard was founded on the result of the Conference. The result was that the possible error could not exceed one-quarter per cent. This was quite within the limits of all practical satisfactory determination. There was no one of the elements in which the trade question could come into prominence which would be practically modified at all by an error of one-quarter per cent., so that for trade purposes the measurement was perfect. With reference to the measurement of quantities, Lord Rayleigh had given them an accurate and trustworthy means of measuring electrical quantities by the electrolysis of silver and copper, and thus the unit of the electric current was now more accurately known. There was another unit called the Board of Trade unit. That was founded on the two that he had referred to, and the foundation of those two being complete, the Board of Trade pressed upon them to adopt a standard. The Act of Parliament ordered them to do this, but it could not possibly be done unless that which they asked for was done, or something equivalent, that would allow the Board of Trade to test with requisite accuracy for practical purposes the instruments which were to be used in the working out of the Electric Light Act.

Sir VINCENT BARRINGTON spoke on behalf of the Electrical Section of the London Chamber of Commerce. He said the Council of the London Chamber were entirely with this movement from a business point of view. He assumed the possibility of these measurements being made accurately. They knew that in France and Germany they were made by the Government, and standards were regulated by the Government, and they felt they could not carry out their contracts without a standard, and it was for that reason that they supported this deputation.

Mr. CROMPTON said, as representing to some extent those companies, namely, the Electrical Supply Companies, that Lord Crawford would have done very much better than himself, he could only corroborate everything that had been said by Lord Rayleigh, Sir William Thomson and Sir Vincent Barrington on the subject. It was quite impossible for them to carry out the provisions of the Model Order which he had lately been studying without having meters certified; and further than that, as a member of the electrical trade or profession, he might say that they were put to disadvantage in competition with those on the other side of the water, who had the advantage of making the whole

Digitized by Google

of their instruments and sending them for certification to Berlin and Paris, at which places Standardising Laboratories had recently been established. Those instruments when thus certified had a higher commercial value in the market of the world, and that fact alone ought to be some argument in favour of asking for this comparatively small sum of money to be expended, and expended if possible during this current year.

Sir MICHAEL HICKS-BEACH: Gentlemen, much that has been said has been, of course, necessarily of a highly technical character, and dealing with matters with which I cannot pretend to be specially conversant. But I think I understand the general purport of your deputation as embodied in the statement which was read by Sir William Thomson. I have only to say that I think in principle there are very good grounds for your request, and more than that I cannot say to-day, but I will look very carefully into it, and I shall, of course, have to bring the subject, if I feel able to do so, before that rather difficult department, the Treasury. I think you have put before me very good grounds for some such decision being made as you have requested.

LORD RAYLEIGH having thanked the right hon. gentleman for his courtesy the deputation withdrew.

THE POEGE ARC LAMP.*

The arc lamp devised by M. Poege, of Chemnitz, is shown diagrammatically in the annexed figure. The mechanism consists of an electro-magnet, A, the coils of which are placed in the main circuit; a circular armature, C; a fine-wire electro-magnet, B; an endless screw, D; a toothed wheel, E; a pulley, K; and a rack, G. When the current passes through the coils of A the armature C is attracted, and the screw D is consequently raised, turning the wheel E slightly and striking the arc. The electro-magnet B, its armature N, and the contact F form a vibrator arrangement, which comes into play whenever the shunt-current is sufficiently powerful—that is to say, whenever the arc becomes too long. These vibrations actuate the rack G, causing the armature C, which is provided with teeth, to rotate. The rotations of the armature cause the screw D to revolve, which in turn communicates its motion to the wheel E. The carbon-holder H, which is fixed to the guide-rod S T, is suspended by a cord wound round the wheel K, so that it now descends and re-establishes the proper length of arc. This lamp is very simple and well made. Its working leaves little to be desired.

AMALGAMATION OF THE TELEPHONE COMPANIES.

The following letter has been addressed to the Secretary of the Post Office, in reply to his communication dated 4th inst., which appeared in *The Electrician* of the 7th :—

"The United Telephone Company (Limited), Oxford-court, Cannon-street, London, E.C., June 1[8], 1889.

"SIR: I am instructed by the directors of the United Telephone Company to acknowledge the receipt of your letter of the 4th instant. The directors are much surprised at the statement made by the Postmaster-General, that the amalgamation of the companies was not contemplated when the licenses were issued. It is impossible to suppose that the legal advisers of the Post Office were ignorant of the fact that it is competent for a company registered under the Joint-Stock Companies' Acts to liquidate and sell its business to another company similarly registered. Such an arrangement is one of almost daily occurrence, and if there had been any intention or desire on the part of the Postmaster-General, when these licenses were granted, to interfere with such an arrangement, the obvious course would have been to have inserted a clause in the license restricting the company's ordinary rights in this respect.

"The directors desire respectfully, but firmly, to join issue with the Postmaster-General on the question of fact. Even if the license had been silent on the subject it would have been impossible to suppose that the legal advisers of the Post Office had overlooked so obvious a point. But, as a matter of fact, the purchase by one company holding a license from the Postmaster-General of the Telephone Exchange business of another company holding a similar license was contemplated, and the license contains clauses (the precise wording of which was the subject of considerable discussion at the time) providing for the consequences which are to happen upon the sale by a company of the whole or of a part of its exchange business. One of these provisions (drawn by the Solicitor of the Department, and inserted after the license was in type) requires that seven days' notice of any such sale shall be given to the Postmaster-General. How, under these circumstances, it can be said that the possibility of such a sale was not contemplated when the licenses were issued, the directors are at a loss to understand.

"The Postmaster-General must surely have overlooked the fact that on three distinct occasions since the granting of these licenses companies or persons holding licenses to carry on the Telephone Exchange business have transferred their exchanges to other companies holding similar licenses without the slightest objection being raised by the Postmaster-General. In all these cases the sale was by a competing company to a company working under the United Telephone Company's patents. In the present case (as the Postmaster-General is aware) there is and can be no competition between the companies uniting, because although each company has a license from the Postmaster-General which entitles it to carry on the exchange business in any part of the United Kingdom, each company, by agreement with the others, works only in its own district. This fact was well known to the department at the time the licences were granted. The directors, therefore, fail to understand to what the Postmaster-General refers when he speaks of the state of things likely to result from the proposed amalgamation. The union will not affect the question of competition between the companies one way or the other, while it will undoubtedly lead to increased economy and efficiency in working.

"In objecting to the exercise by a Joint-Stock Company of its undoubted right to transfer its business to another company the Postmaster-General is seeking to impose upon the telephone companies the restrictions of a Parliamentary character without any of its privileges. As the Postmaster-General is aware, the United Telephone Company has more than once applied to Parliament for incorporation upon the lines recommended by the Parliamentary Committee which investigated the matter and reported in the year 1885, but the Postmaster-General has consistently opposed these applications.

"The directors venture to suggest that the interests of the public would be better served if the heavy tax imposed by the Department upon telephonic communication (a tax which is obviously really paid by the public in the shape of increased charges) were removed, and reasonable facilities were granted to the telephone companies, which would enable them to give to the public a cheaper and a better service. The directors have loyally carried out the engagements which they entered into with the Department when the terms of the present license were, after much consideration, settled by the late Mr. Fawcett, and they are unwilling to believe that the present Postmaster-General will attempt to reverse the policy of his predecessors, or to withdraw from any assurance, honourable or legal, given by the Department.—I am, Sir, yours obediently,

"THOS. BLAIKIE, Secretary.

"Sir S. Arthur Blackwood, K.C.B., General Post Office."

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

THE POSTMASTER-GENERAL AND THE TELEPHONE.

The hope we expressed only a fortnight ago that public attention would soon be directed to the question of the future of the Telephone has not had long to remain unsatisfied. Both the financial and political press have commented freely on Sir ARTHUR BLACKWOOD'S letter of the 4th inst., and the reply of the United Telephone Company's directors, which appeared in last Monday's *Times*, called forth in that journal the same day a leading article which is calculated to attract general attention to the importance of the question at issue. The matter now rests with the POSTMASTER-GENERAL, and as he can hardly afford to allow the United Telephone Company's letter to remain unanswered, we hope he will take the opportunity to express in more explicit terms his objections to the proposed amalgamation; and, what is of even greater importance, what he proposes to do supposing it is carried out in spite of his remonstrance.

As to the terms of his remonstrance—or warning, as it may be more fitly described—we are bound to say they were equally ambiguous on both the points referred to. If Mr. RAIKES' legal advisers were in the least doubt as to the legality of the proposed scheme, the companies themselves may well be excused the assumption that they are within their legal rights.

Digitized by Google

The legal interpretation of the licenses is the very essence of the present dispute; and we strongly suspect that the public will share the view expressed by *The Times* that it would be very unfair to the companies to punish them for a defect in the wording of the licenses for which the departmental advisers were solely responsible. For this is really what the POSTMASTER-GENERAL, through Sir A. BLACKWOOD, seemed to contemplate in the second point to which he directs the companies' attention. Whether the amalgamation, he says, is legal or not, it was not contemplated when the licenses were issued; and any assurances given at that time cannot be regarded as applicable to the state of things likely to result from the proposed amalgamation. *The Times* interprets this as cancelling the original assurances that the rights of purchase reserved by the Post Office for the years 1890, 1897, or 1904, would not be exercised if a satisfactory public service were established, and as indicating that Mr. RAIKES intends to apply them on the earliest opportunity. Evidently some such understanding is referred to, and a threat of some kind is veiled under the statement that the changed circumstances, if carried into effect, will make the pledge no longer binding. But whatever it may have been, we think Mr. RAIKES has under-estimated the honourable obligation which is imposed on a public department by a promise of this kind, although not embodied in any legal document relating to the transaction. The public will take the view that the Post Office is bound by its promise, supposing it can be shown that the Post Office made it, and under conditions not now positively violated by the other parties.

Of course the question here arises, assuming the existence of "assurances outside the licenses," Are the companies abiding by their own outside, or implied, assurances, in attempting to amalgamate themselves into one solid corporation? Mr. BLAIKIE, speaking for the directors of the United Company, protests that they are breaking no understanding whatever, that the several companies have constituted a virtual monopoly all along, each in its own district, and that the projected amalgamation will make no practical difference in this respect, but will tend to benefit the public by reducing working expenses, and improving the telephonic service by consolidating it. These contentions are strictly true, and if the companies occupied the position of ordinary joint-stock traders, which is the attitude curiously taken up in Mr. BLAIKIE's letter, their position would be unassailable. But they forget they are arguing with one who knows perfectly well that this is not their position, and that they are trading only on a limited sufferance, and by the grace of Parliament, represented by the POSTMASTER-GENERAL for the time being. And the present POSTMASTER-GENERAL happens to conceive it to be his duty in the public interest to guard against some danger, the nature of which he does not specifically define, but which may easily be conjectured to be not precisely the one referred to by the companies themselves. No doubt the result of this correspondence will be to compel him to announce what it is that he apprehends and desires to avert. The public will then be able to judge between him and the companies; and it is quite time they were allowed to do so, for they are certainly entitled to be telephonically served either by the companies or by the Post Office; and this very interposition of the Post Office authorities shows that the time has arrived when the public ought to know which it is to be.

It will be seen that in the main we agree with the criticisms of our contemporary, *The Times*, so far as the published correspondence is concerned; but we strongly demur to its concluding deduction that a monopoly of the telephone service is undesirable either in the hands of the companies or of the Post Office. We do not pretend to say whether, had the Post Office retained its rights in the Telephone, the monopoly would have been worked to public advantage—though so far as the technical officers of the Post Office are concerned we need hardly say that we have every confidence in their ability to deal with the problem—but we are distinctly of opinion that by permitting a practical monopoly to the several telephone companies in their respective areas the public have been spared a most pernicious and ruinous competition, with an unendurable aggravation of the overhead wire nuisance. It should be noticed that Sir A. BLACKWOOD himself says nothing about monopoly; the word does not occur in his letter. What he is instructed to object to is amalgamation, which, he says, was not contemplated when the licenses were issued. The distinction has been practically maintained all along, the Post Office granting licenses which covered the whole country, but allowing private agreements between the parties that none would invade the territory of the others. Thus there has been what may be called competition by comparison in actual operation, and a potential competition of an active sort in reserve. The competition of the Post Office itself has never been seriously pushed save in one or two quarters; and the fact is at once creditable to the companies and proof that in the opinion of the Post Office "a real competition among telephone companies," such as is advocated by *The Times*, would have "delighted" nobody else. This being the policy and practice of the Post Office for the past nine years, we cannot suppose that any revolutionary change is contemplated now. All the more reason, however, for Mr. RAIKES to make known what is the change he actually does foreshadow in the enigmatical utterances with which he has recently startled and perplexed the telephonic world.

THE USES OF THE VOLTAIC BALANCE.

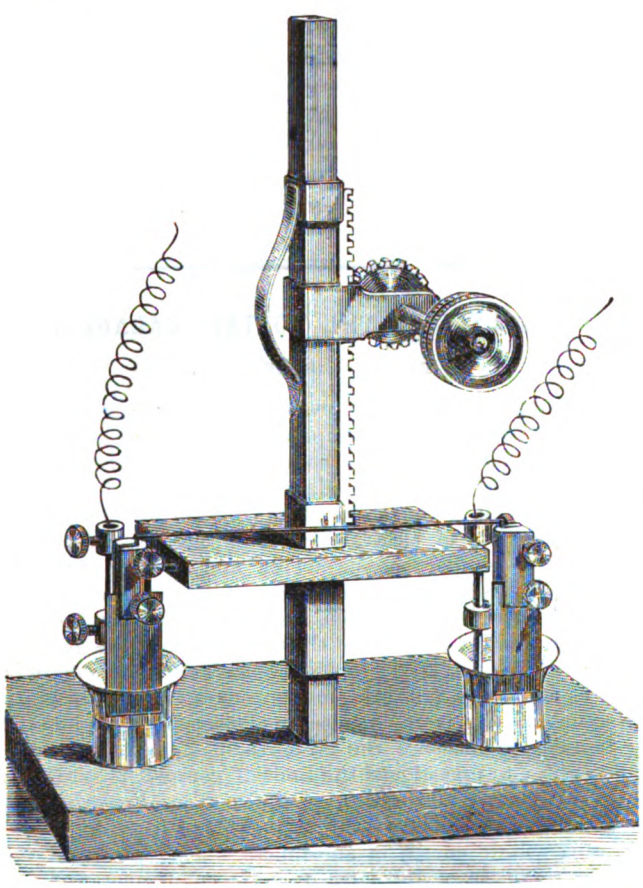
BY DR. G. GORE, F.R.S.

This instrument (sketch) is capable of being used for a variety of purposes. It has been employed for measuring the relative amounts of voltaic energy of aqueous solutions of many kinds of simple substances, compounds and mixtures (*see* Royal Society *Proceedings*, Vol. XLV., pp. 268, 442); to form volta tension series of a large variety of electrolytes, simple and compound (*ibid.*); for making similar measurements and tension series with different metals and alloys in such solutions; to discover chemical compounds in solution, and determine the combining proportions and valencies of their ingredients, the basicity of acids, &c. (*ibid.*, p. 265); to distinguish between chemical compounds and mere mixtures in aqueous solution; to assist in detecting substances in chemical analysis; to detect impurities in liquids; to measure the strength of aqueous solutions of substances; to investigate the limit of complexity of dissolved chemical compounds (*ibid.*, p. 266; also *Proceedings* Birmingham Philosophical Society, Vol. VI.); to measure losses of voltaic energy of substances during chemical union (*ibid.*); to discover dissolved isomeric compounds and detect differences of internal molecular structure of liquids (Royal Society *Proceedings*, Vol. XLV., p. 267); to discover unstable and spontaneously decomposable mixtures in solution (*ibid.*); to investigate the distribution of acids and bases in aqueous solution; to detect changes of chemical composition and measure losses and gains of voltaic energy of electrolytes, caused by heat, oxidation, deoxidation, or other influences, and measure the rates of chemical change (*ibid.*, p. 440); to detect and measure such changes in liquids, and their rates, during exposure to light or radiant heat, and investigate the influence of the nature, thickness, and colour of screens, etc.; probably also to measure the relative amounts of chemical energy of dissolved substances when uniting with metals; and for other purposes.

The method of measuring the amount of voltaic energy of a substance is as follows:—Take two small glass cups containing known volumes of distilled water. Form two voltaic

Digitized by Google

cells of them by means of strips or stout wires of unamalgamated zinc cut from the same piece, and two small sheets of platinum also cut from the same piece. Connect them in series to a sufficiently sensitive galvanometer, say one of from 100 to 1,000 ohms resistance, so that the currents from the two cells oppose each other and produce no visible deflection of the needles. This arrangement constitutes a "voltaic balance," and is extremely sensitive to change of chemical composition of the liquid in one of the vessels. Make an aqueous solution of known strength of the substance the energy of which is to be measured, and add it in sufficiently small quantities at a time to the water in one of the cups until the needles of the galvanometer visibly commence to move, and note the proportion of the substance and of water then contained in that vessel. As the amount of energy required to move the needles is the same in all cases, the different numbers thus obtained with different substances represent the relative amounts of voltaic energy of those substances under the same conditions, viz., kind of voltaic couple, galvanometer, and degree of temperature. The greater the proportion of water required to reduce the voltaic energy to the same amount, the greater is the voltaic energy of the substance (Royal Society *Proceedings*, Vol. XLV., pp. 268, 442). Care must be taken by occasionally heating the platinum to redness to avoid error caused by absorption of hydrogen.



Dr. Gore's Voltaic Balance.

By its aid, the voltaic influence upon magnesium of one part by weight of chlorine in 500,000 million parts of water has been detected; and the method is so sensitive, and the quantity of liquid required is so small, that "it would be easy to detect the effect of less than one ten-thousand-millionth of a grain of chlorine in one-tenth of a cubic centimetre of distilled water by this process" (*ibid.*, Vol. XLIV., p. 151). By removing the cups, substituting for them a horizontal strip of sheet platinum, placing a drop of distilled water upon one end, a drop of extremely dilute chlorine water upon the other end, and lowering two strips of sheet magnesium instead of zinc simultaneously into contact with the two liquids, and employing a very sensitive galvanometer, the total weight of chlorine necessary would be very much smaller than the amount mentioned.

To make the proper strength of chlorine water, take a freshly-made and pure solution, about three-fourths saturated, of known strength, and perfectly free from hydrochloric acid. Dilute it with distilled water in a tall and narrow graduated glass vessel to one part by weight in 1,000 parts of water. Add one part of this liquid to 999 parts of such water in a second similar vessel. Add one part of this second liquid to 999 parts of water in a third vessel; and use this third liquid to add to a suitable proportion of water in one of the cups of the balance. If the chlorine water contains any dissolved impurity its voltaic energy will be considerably diminished.

By the balance method has been measured the relative amounts of voltaic energy of more than 500 definite compounds and mixtures in aqueous solution—of elements with elements; elements with monobasic, bibasic, and tribasic acids; acids of all those classes with each other; elements with monobasic, bibasic, tribasic, and tetrabasic salts; monobasic, bibasic, and tribasic acids, with all these classes of salts; and all these salts with each other in similar great variety; and from the numbers thus obtained, volta tension series of these liquids with zinc and platinum have been formed, ranging in amount of energy from chlorine with a plus number of 1,282,000,000 to a certain mixture of salts which gives a minus number of – 959,817 (*ibid.*, Vol. XLV., p. 268).

In such series the halogens head the list, the acids come next then follow in succession acid salts, neutral salts, and then water, which forms the zero of the plus magnitudes; then come the alkaline salts, and finally the alkalies and their compounds, all giving minus numbers. With all members of the series above water, the electromotive force of the charged cell overcomes that of the water cell, whilst with all those below water the current from the latter cell overpowers that of the former and reverses the direction of deflection of the needles.

The method of discovering dissolved chemical compounds, and ascertaining their combining proportions by means of the "voltaic balance," is based upon the general truth that *when substances chemically combine they lose some of their voltaic energy or power of exciting a voltaic couple.*

The method is briefly as follows: "Dissolve in separate, equal, and known quantities of distilled water a series of several mixtures of the two constituents A and B of the supposed compound, in the proportion of their atomic or molecular weights and multiples of them, some having an excess of A and others of B. For instance, if both are monads, mix them in the several proportions represented by the formulæ 5 A + 4 B, 4 A + 4 B, and 4 A + 5 B; but if A is a monad and B a dyad, then use the proportions indicated by 3 A + 2 B, 4 A + 2 B, and 5A + 2 B."

"Add sufficiently minute quantities in succession of one of these solutions to the water of one of the voltaic couples until the needles of the galvanometer visibly commence to move and note the proportion added. Recharge the vessel with distilled water, clean the metals, and repeat the experiment with another of the solutions, and so on until all the solutions have been tried and the mixture has been found of which the largest proportion is required to move the needles; this is the one which has the smallest proportion of voltaic energy, has lost most energy by chemical union, and which has its constituents most strongly combined and chemically united in the usual definite proportions by weight, without an excess of either ingredient in a chemically free state." Mixtures may be known by their ingredients not being in the proportions of the ordinary chemical equivalents, and partly by their magnitudes of voltaic energy in relation to that of the true compound being usually larger. "The method may be used to ascertain the degrees of valency of substances, the basicity of acids, &c." (Royal Society *Proceedings*, Vol., XLV., p. 267).

By means of this instrument several hundreds of new chemical compounds, existing only whilst dissolved in water, and therefore termed "solution compounds," have been discovered, and a large amount of evidence has been obtained, supporting the conclusions "that there may probably be discovered thousands of such compounds, which exist only whilst in aqueous solution, and are decomposed on evaporating or crystallising their solution," and "*that every such electrolytic substance or mixture, when dissolved in water, unites chemically in de-*

Digitized by Google

finite proportions by weight with every other such dissolved body," provided no separation of substance occurs (*ibid.*, p 267). A list of nearly 250 of these predicted substances, the existence of which has since been proved, has been communicated to the Royal Society (*ibid.*, p. 422), and many others have since been similarly found.

In the hundreds of instances yet examined, not a single one has been observed in which definite chemical union between two soluble substances has not been more or less clearly indicated by a minimum amount of voltaic energy, coinciding with the ordinary chemical equivalents of the substances; and this has occurred however complex the composition of the dissolved bodies.

As each substance in a pure state has, under the above-named conditions, a definite proportion of voltaic energy, and any soluble substance added in small amount to its solution diminishes that proportion, an impure substance can be readily detected by comparing it with the pure one in the voltaic balance. A given amount of energy alone, is not however, a characteristic test of a substance, except perhaps with chlorine, because several mixtures may give the same amount.

The method of determining the strength of liquids by means of this instrument is based upon the circumstance, that the greater the degree of concentration of a solution the larger is the amount of dilution required to reduce its voltaic energy to a given magnitude. For instance, the quantity of water required with one part of undiluted sulphuric acid, H^2SO^4, in one of the cups, in order to just visibly move the needles of the galvanometer, was 3,900,941 parts; if, therefore, the specimen of dilute acid required only half that proportion of water in order to produce that effect, it contained 50 per cent. of H^2SO^4. In using this method, it is necessary to know beforehand the amount of voltaic energy under the given conditions, either of the pure substance, or if it is impure, that of the particular undiluted sample.

In determining the degree of strength of solutions by this method, a much smaller amount of the dissolved substance is usually necessary than is required when it is determined either by that of specific gravity or by chemical analysis (see *Electrician*, Vol. 23, p. 71).

In order to examine the limit of complexity of composition of "solution compounds," two substances A and B are mixed together in the proportion of their chemical equivalents, and the amount of voltaic energy of the compound measured. A third substance in chemically equivalent amount to the first compound is now added, and the voltaic energy similarly measured. A fourth substance in equivalent proportion to the second compound is further added, and the energy also measured; and so on to any extent of complexity that may be convenient to examine. In all such cases, no substance should be added which causes a loss of dissolved matter, either by precipitation or by evolution of gas. As each successive addition of a new ingredient or increase of degree of complexity of the compound formed is attended by a loss of voltaic energy, this process is also a method of measuring the amounts of loss of such energy during chemical union.

By its means has been shown that there exists no apparent limit to the degree of complexity of "solution compounds," definite substances having been found possessing compositions represented by the formulæ, 4 K^2CrO^4; Na^2SO^4; K^2SO^4; 2 NaCl KCl; 8 K^2CO^3 (*Proceedings* Birmingham Philosophical Society, Vol. VI.); and K^2SO^4; 2 NaCl; 4 AmCl; 8 KCl; 16 KNO^3; 32 LiCl (Royal Society *Proceedings*, Vol. XLV., p. 266), thus rendering probable the inference that chemical affinity, feeble in degree, operates between large collections or aggregates of dissimilar molecules, provided the uniting aggregates are in the definite proportions by weight of the ordinary chemical equivalents.

Illustrations of the mode of detecting isomeric mixtures in solution have been communicated to the Royal Society (*ibid.*, p. 267).

Nearly every change of chemical composition of an electrolyte is attended by change of amount of voltaic energy. In order, therefore, to measure the rate of chemical change spontaneously going on in an aqueous solution—for instance, that of a mixture of equal proportions of potassic iodide and chlorine—we have to keep the solution in a stoppered glass bottle at an uniform temperature in the dark, and measure its voltaic energy at uniform intervals of time. By plotting as ordinates and abscissæ the losses of energy and the periods of time required, a curve of the rate of chemical change can be obtained. To ascertain the rate of change caused by heat, immerse a similarly-charged bottle in hot water, remove and cool it, and measure the energy, and so on repeatedly from time to time (Royal Society's *Proceedings*, Vol. XLV., pp. 440-441). By employing a liquid which is decomposed by light, such as chlorine water, the voltaic balance may be used to measure the intensity of light. The methods of using the instrument in measuring the rate of chemical change produced in liquids by light, radiant heat, oxidation, &c., are obvious from the information already given.

Other applications of the instrument to scientific research and to practical purposes remain to be made.

Messrs. Elliott, Brothers, St. Martin's-lane, London, have undertaken to make the instrument.

ON MODERN VIEWS WITH RESPECT TO THE NATURE OF ELECTRIC CURRENTS.*

BY PROF H. A. ROWLAND.

As, a short time since, I stood in a library of physical books, and glanced around me at the works of the great masters in that subject, my mind wandered back to the time when the apparatus for a complete course of lectures on the subject of electricity consisted of a piece of amber and a few light bodies to be attracted by it. From that time until now, when we stand in a magnificent laboratory with elaborate and costly apparatus in great part devoted to its study, how greatly has the world changed and how our science of electricity has expanded both in theory and practice, until, in the one case, it threatens to include within itself nearly the whole of physics, and in the other to make this the age of electricity.

Were I to trace the history of the views of physicists with respect to electric currents it would include the whole history of electricity. The date when the conception of an electric current was possible was that when Stephen Gray, about 170 years ago, first divided bodies into conductors and non-conductors, and showed that the first possessed the property of transmitting electric attractions to a distance. But it was only when the Leyden jar was discovered that the idea of a current became very definite. The notion that electricity was a subtle fluid which could flow along metal wires as water flows along a tube was then prevalent, and, indeed, remains in force to-day among all except the leaders in scientific thought. It is not my intention to depreciate this notion, which has served, and still serves, a very important purpose in science. But for many years it has been recognised that it includes only a very small portion of the truth, and that the mechanism by which energy is transmitted from one point of space to another by means of an electric current is a very complicated one.

Here, for instance, on the table before me are two rubber tubes filled with water, in one of which the water is in motion and the other at rest. It is impossible by any means now known to us to find out, without moving the tubes, which one has the current of water flowing in it and which has the water at rest. Again, I have here two wires, alike in all respects, except that one has a current of electricity flowing in it and the other has not. But in this case I have only to bring a magnetic needle near the two to find out in which one the current is flowing. On our ordinary senses the passage of the current has little effect; the air around it does not turn green or the wire change in appearance. But we have only to change our medium from air to one containing magnetic particles to perceive the commotion which the presence of a current may cause. Thus this other wire passes through the air near a large number of small suspended magnets, and, as I pass the current through it, every magnet is affected and tends to turn at right angles to the wire and even to move toward it and wrap itself around it. If we suppose the number of these magnets to become very great and their size small, or if we imagine a medium, every atom of which is a magnet, we see that no wire carrying a current of electricity can pass through it without creating the greatest commotion. Possibly this is a feeble picture of what takes place in a mass of iron near an electric current.

Again, coil the wire around a piece of glass, or, indeed, almost any transparent substance, and pass a strong current through the wire. With our naked eye alone we see no effect whatever, as the

* A lecture given at the College of the City of New York, May 22, 1889, before the American Institute of Electrical Engineers.

Digitized by Google

glass is apparently unaltered by the presence of the current, but, examined in the proper way by means of polarised light, we see that the structure of the glass has been altered throughout in a manner which can only be explained by the rotation of something within the glass many millions of times every second.

Once more, bring a wire in which no current exists nearer and nearer to the one carrying the current, and we shall find that its motion in such a neighbourhood causes, or tends to cause, an electric current in it. Or, if we move a large solid mass of metal in the neighbourhood of such a current we find a peculiar resistance unfelt before, and if we force it into motion we shall perceive that it becomes warmer and warmer as if there was great friction in moving the metal through space.

Thus, by these tests, we find that the region around an electric current has very peculiar properties which it did not have before, and which, although stronger in the neighbourhood of the current, still extend to indefinite distances in all directions, becoming weaker as the distances increase.

How great, then, the difference between a current of water and a current of electricity. The action of the former is confined to the interior of the tube, while that of the latter extends to great distances on all sides, the whole of space being agitated by the formation of an electric current in any part. To show this agitation, I have here two large frames with coils of wire around them. They hang face to face about 6ft. apart. Through one I discharge this Leyden jar, and immediately you see a spark at a break in the wire of the other coil, and yet there is no apparent connection between the two. I can carry the coils 50ft. or more apart, and yet, by suitable means, I can observe the disturbances due to the current in the first coil.

The question is forced upon us as to how this action takes place. How is it possible to transmit so much power to such a distance across apparently unoccupied space? According to our modern theories of physics there must be some medium engaged in this transmission. We know that it is not the air, because the same effects take place in a vacuum, and, therefore, we must fall back on that medium which transmits light and which we have named the ether—that medium which is supposed to extend unaltered throughout the whole of space, whose existence is very certain, but whose properties we have yet but vaguely conceived.

I cannot, in the course of one short hour, give even an idea of the process by which the minds of physicists have been led to this conclusion, or the means by which we have finally completely identified the ether which transmits light with the medium which transmits electrical and magnetic disturbances. The great genius who first identified the two is Maxwell, whose electro-magnetic theory of light is the centre around which much scientific thought is to-day revolving, and which we regard as one of the greatest steps by which we advance nearer to the understanding of matter and its laws. It is this great discovery of Maxwell which allows me, at the present time, to attempt to explain to you the wonderful events which happen everywhere in space when one establishes an electric current in any other portion.

In the first place, we discover that the disturbance does not take place in all portions of space at once, but proceeds outwards from the centre of the disturbance with a velocity exactly equal to the velocity of light; so that, when I touch these wires together so as to complete the circuit of yonder battery, I start a wave of etherial disturbance which passes outward with a velocity of 185,000 miles per second, thus reaching the sun in about eight minutes, and continuing to pass outwards for ever, or until it reaches the bounds of the universe. And yet none of our senses inform us of what has taken place unless we sharpen them by the use of suitable instruments. Thus, in the case of these two coils of wire, suspended near each other, which we have already used, when the wave from the primary disturbance reaches the second coil we perceive the disturbance by means of the spark formed at the break in the coil. Should I move the coils further apart, the spark in the second coil would be somewhat delayed, but the distance of 185,000 miles would be necessary before this delay could amount to as much as one second. Hence the effects we observe on the earth take place so nearly instantaneously that the interval of time is very difficult to measure, amounting in the present case to only $\frac{1}{1500000}$th of a second.

It is impossible for me to prove the existence of this interval, but I can at least show you that waves have something to do with the action here observed. For instance, I have here two tuning-forks mounted on sounding-boxes and tuned to exact unison. I sound one and then stop its vibrations with my hand; instantly you hear that the other is in vibration, caused by the waves of sound in the air between the two. When, however, I destroy the unison by fixing this piece of wax on one of the forks the action ceases.

Now, this combination of a coil of wire and a Leyden jar form a vibrating system for electricity, and its time of vibration is about 10,000,000 times a second. This second system is the same as the first, and therefore its time of vibration is the same. You see how well the experiment works now because the two are in unison. But let me take away this second Leyden jar, thus destroying the unison, and you see that the sparks instantly cease. Replacing it, the sparks reappear. Adding another on one side, and they disappear again, only to reappear when the system is made symmetrical by placing two on each side.

This experiment and that of the tuning-forks have an exact analogy to one another. In each we have two vibrating systems connected by a medium capable of transmitting vibrations, and they both come under the head of what we know as sympathetic vibrations. In the one case, we have two mechanical tuning-forks connected by the air; in the other, two pieces of apparatus, which we might call electrical tuning-forks, connected by the luminiferous ether. The vibrations in one case can be seen by the eye or heard by the ear, but in the other case they can only be perceived when we destroy them by making them produce a spark. The fact that we are able to increase the effect by proper tuning demonstrates that vibrations are concerned in the phenomenon. This can, however, be separately demonstrated by examining the spark by means of a revolving mirror, when we find that it is made up of many successive sparks corresponding to the successive backward and forward movements of the current.

The fact of the oscillatory character of the Leyden jar discharge was first demonstrated by our own countryman, Henry, in 1832, but he pursued the subject only a short distance, and it remained for Sir William Thomson to give the mathematical theory and prove the laws according to which the phenomenon takes place.

Thus, in the case of a charged Leyden jar whose inner and outer coatings have been suddenly joined by a wire, the electricity flows back and forth along the wire until all the energy originally stored up in the jar has expended itself in heating the wire or the air where the spark takes place and in generating waves of disturbance in the ether which move outward into space with the velocity of light. These etherial waves we have demonstrated by letting them fall on this coil of wire and causing the electrical disturbance to manifest itself by electric sparks.

I have here another more powerful arrangement for producing electro-magnetic waves of very long wave length, each one being about 500 miles long. It consists of a coil within which is a bundle of iron wires. On passing a powerful alternating current through the coil the iron wires are rapidly magnetised and demagnetised, and send forth into space a system of electro-magnetic waves at the rate of 360 in a second.

Here, also, I have another piece of apparatus for sending out the same kind of electro-magnetic waves, and, on applying a match, we start it also into action.* But the last apparatus is tuned to so high a pitch that the waves are only $\frac{1}{50000}$ inch long, and 55,000,000,000,000 are given out in one second. These short waves are known by the name of light and radiant heat, though the name radiation is more exact. Placing any body near the lamp, so that the radiation can fall on it, we observe that when the body absorbs the rays it is heated by them; the well-known property of so-called radiant heat and light. Is it not possible for us to get some substance to absorb the long waves of disturbance, and so obtain a heating effect? I have here such a substance in the shape of a sheet of copper, which I fasten on the face of a thermopile, and I hold it where these waves are the strongest. As I have anticipated, great heat is generated by their absorption, and soon the plate of copper becomes very warm, as we see by this thermometer, by feeling it with the hand, or even by the steam from water thrown upon it. In this experiment the copper has not touched the coil, or the iron wire core, although if it did they are very much cooler than itself. The heat has been produced by the absorption of the waves in the same way as a blackened body absorbs the rays of shorter wave length from the lamp, and in both cases heat is the result.

But in this experiment, as in the first one, the wave-like nature of the disturbance has not been proved experimentally. We have caused electric sparks, and have heated the copper plate across an interval of space, but have not in either of these cases proved experimentally the progressive nature of the disturbance.

A ready means of experimenting on the waves, obtaining their wave length and showing their interferences, has hitherto been wanting. This deficiency has been recently overcome by Prof. Hertz, of Carlsruhe, who has made a study of the action of the coil, and has shown us how to use it for experiments on the etherial waves whose existence had before been made certain by the mathematics of Maxwell.

I scarcely know how to present this subject to a non-technical audience and make it clear how a coil of wire with a break in it can be used to measure the velocity and wave length of etherial waves. However, I can but try. If the waves moved very slowly, we could readily measure the time the first coil took to affect the second, and show that this time was longer as the distance was greater. But it is absolutely inappreciable by any of our instruments, and another method must be found. To obtain the wave length, Prof. Hertz used several methods, but that by the formation of stationary

* The lecturer here lit a gas flame.

Digitized by Google

waves is the most easily grasped. Mr. Ames holds in his hand one end of a spiral spring, which makes a very heavy and flexible rope. As he sends a wave down it, you see that it is reflected at the further end, and returns again to his hand. If, however, he send a succession of waves down the rope, the reflected waves interfere with the direct ones, and divide the rope into a succession of nodes and loops, which you now observe. So a series of sound waves, striking on a wall, form a system of stationary waves in front of the wall. Indeed, we can use any waves for this purpose, even etherial waves. With this in view Prof. Hertz established his apparatus in front of a reflecting wall, and observed the nodes and loops by the sparks produced in a ring of wire, somewhat resembling the coil I have been using on the present occasion, but much smaller. It is impossible for me to repeat this experiment before you, as it is a very delicate one, and the sparks produced are almost microscopic. Indeed, I should have to erect an entirely different apparatus, as the waves from the one before me are nearly quarter-mile long, the time of vibration of the system being very great, that is $\frac{1}{100000000}$th of a second. To produce shorter waves, we must use apparatus tuned, as it were, to a higher pitch, in which the same principle is, however, employed, but the etherial waves are shorter, and thus several stationary waves can be contained in one room.

The testing coil is then moved to different portions of the room, and the nodes are indicated by the disappearance of the sparks, and the loops by the greater brightness of them. The presence of stationary waves is thus proved, and their half waves length found from the distance from node to node, for stationary waves can always be considered as produced by the interference of two progressive waves advancing in opposite directions.

However interesting a further description of Prof. Hertz's experiments may be, we have gone as far in that direction as our subject carries us, for we have demonstrated that the production of a current in a wire is accompanied by a disturbance in the surrounding space; and although I have not experimentally demonstrated the etherial waves, yet I have proved the existence of electric oscillations in the coil of wire and the ether surrounding it.

Our mathematics have demonstrated, and experiments like those of Prof. Hertz have confirmed the demonstration, that the wave disturbance in the ether is an actual fact.

The closing of a battery circuit, then, and the establishment of a current of electricity in a wire, is a very different process from the formation of a current of water in a pipe, though after the first shock the laws of the flow of the two are very much alike. But even then the medium around the current of electricity has very strange properties, showing that it is accompanied by a disturbance throughout space. The wire is but the core of the disturbance, which latter extends indefinitely in all directions.

One of the strangest things about it is that we can calculate with perfect exactness the velocity of the wave propagation and the amount of the disturbance at every point and at any instant of time; but as yet we cannot conceive of the details of the mechanism which is concerned in the propagation of an electric current. In this respect our subject resembles all other branches of physics in the partial knowledge we have of it. We know that light is the undulation of the luminiferous ether, and yet the constitution of the latter is unknown. We know that the atoms of matter can vibrate with purer tones than the most perfect piano, and yet we cannot even conceive of their constitution. We know that the sun attracts the planets with a force whose law is known, and yet we fail to picture to ourselves the process by which it takes our earth within its grasp at the distance of many millions of miles and prevents it from departing for ever from its life-giving rays. Science is full of this half-knowledge, and the proper attitude of the mind is one of resignation toward that which it is impossible for us to know at present, and of earnest striving to help in the advance of our science, which shall finally allow us to answer all these questions.

The electric current is an unsolved mystery, but we have made a very great advance in understanding it when we know that we must look outside of the wire at the disturbance in the medium before we can understand it—a view which Faraday dimly held fifty years ago, which was given in detail in the great work of Maxwell, published sixteen years since, and has been the guide to most of the work done in electricity for a very long time—a view which has wrought the greatest changes in the idea which we have conceived with respect to all electrical phenomena.

The Lighting of the "Victoria and Albert."—According to the *World*, the electric light machinery on the Royal yacht "Victoria and Albert," "which was so noisy that the Queen vowed that she would never again sleep on board until it was removed," has been transferred to the Admiralty yacht "Enchantress."

ELECTRIC MOTOR REGULATION.*

BY FRANCIS B. CROCKER.

(*Continued from page 148.*)

The second table gives a list of the possible cases of motor regulation which may occur with direct or continuous currents. There are four supremely important quantities or conditions in connection with electric motor regulation, viz., potential, current, speed and load, and it is with reference to one or more of these that practically all motors are designed, built, sold and used. Motors are always distinguished, both in science and in trade, as constant-potential or constant-current motors; constant or variable speed motors, and constant variable load motors; hence a classification of motors based upon the constancy or variability of these four factors is very convenient, and at the same time scientifically correct. The second table is made upon this plan, and in it the four quantities are represented by their initial letters P, C, S and L, expressed respectively in volts, amperes, revolutions per minute and torque in pounds at one foot radius, these being the units ordinarily used in practical as well as scientific work. We find that there are in all sixteen different cases, in the first four of which the potential is constant, in the second four the potential and current are both constant, in the third four the current only is constant, and in the fourth four neither the current nor the potential is constant.

TABLE II.—List of Possible Cases with Direct Currents.

P = Difference of potential in volts at terminals of motor.
C = Current in amperes supplied to motor.
S = Speed of armature in revolutions per minute.
L = Load or torque in lbs. at one foot radius.

Any of these four quantities may be either constant or variable, making the following combinations:—

Case.	Constant.	Variable.	Example.
1.	P	C S L	Series wound motor with variable load on constant potential circuit.
2.	P S	C L	Shunt or compound-wound motor with variable load on constant potentia circuit.
3.	P L	C S	Shunt motor with constant load and variable field resistance on constant-potential circuit.
4.	P S L	C	Not practical.
5.	P C	S L	Not likely to occur.
6.	P C S	L	Impossible.
7.	P C L	S	Impossible.
8.	P C S L		Shunt motor with constant load on constant-potential circuit.
9.	C	P S L	Shunt motor with variable load on constant-current circuit.
10.	C S	P L	Series motor with speed governor and variable load on constant-current circuit.
11.	C L	P S	Series on arc constant torque.
12.	C S L	P	Not practical.
13.	S	P C L	Motor with speed governor and variable load on circuit of variable potential and current.
14.	S L	P C	Motor with constant load and speed governor on circuit of variable potential and current.
15.	L	P C S	Motor with constant load without speed governor on circuit of variable potential and current.
16.		P C S L	Motor with variable load without speed governor on circuit of variable potential and current.

Case 1, in which the potential alone is constant, is the case of a series-wound motor, for example, with variable load on a constant potential circuit. Such a motor would rise in speed when the load was reduced, and *vice versâ*. It would not be at all self-regulating—in fact, it would tend to run at a very high speed with light load, and a very low speed with a heavy load. It is possible to give various other examples, but one is sufficient in most cases. In this case, however, I may say that the ordinary street-car motor, fed from a constant-potential circuit, is also an example of Case 1, the current being controlled by varying the external or internal resistance according to one of the methods given in the first table.

Case 2 is that of the ordinary shunt or differential motor, with a variable load on a constant-potential circuit. This is self-regulating and maintains its constant speed, as already stated, and is the com-

* A Paper read before the American Institute of Electrical Engineers New York, May 22, 1889.

Digitized by Google

monest case of motor regulation met with. The current varies directly with the load.

Case 3 is that of the ordinary shunt motor with constant load, having a variable resistance in the field magnet. This case is shown in Fig. 1. Increasing resistance of field circuit would weaken the field magnetism, and the motor would run faster and take more current, *i.e.*, current would vary directly with speed.

Case 4 is not a practical one, because, if potential speed and load are constant, the current cannot be varied without wasting it—that is, any excess of current would be simply destroyed, which, of course, is not permissible.

Case 5 is not likely to occur, because potential and current would not be constant with a variable load and speed, but if it did occur it would require that the speed and load should vary inversely.

Cases 6 and 7 are not practical, for the same reason as given in Case 4, because if potential current and speed were constant the load could not be reduced without wasting electrical energy, and in Case 7 the speed could not be varied without wasting energy.

Case 8 is that in which all four factors are constant, and is best illustrated by a shunt motor with constant load on a constant-potential circuit, in which case the current and speed would also be constant.

Case 9 may be illustrated by a shunt motor with variable load on a constant-current circuit. The speed would run up as the load reduced. A more common example is a series motor on constant-current circuit, with switch for cutting out field coils, or, in short, a constant-current motor with variable speed and load.

Case 10 is that of the regular constant-current or "arc" motor with governor, such, for example, as the Baxter or "C. and C.;" it is a series motor with a centrifugal governor which operates a switch to cut in and out the field coils as shown in Fig. 3. This is, next to the shunt and differential-wound motors, the most common and important case of motor regulation.

Case 11 is that of a constant-current motor with constant load, with switch for varying field strength. The potential would rise directly with speed, but this case is not likely to occur.

Case 12 is not practical for the same reason as given in Case 4.

The last four cases are those in which both potential and current vary. They are hardly practical cases, because electrical distribution is almost always either at constant current or constant potential. It is, however, of course possible to have cases where both may vary, and examples of each case are given.

Case 13 is one which does occur to a certain extent in practice; for example, if a so-called constant-current circuit varies slightly, as it always does in practice, say from 9 to 10 amperes, then the current as well as potential is variable to that extent, and this must be taken into account in the regulation.

In the experiments which I have already referred to, Mr. Wheeler and I have built a motor of the constant current type which will govern for wide variations in current as well as in load. This motor, for example, will not fall in speed, even though the current be reduced from 10 to 5 amperes, which is a great variation for this type of motor, as the field and armature being in series, the torque varies as the square of the current. This variation in current in the so-called constant-current circuits is a much greater percentage than the variation in potential of so-called constant-potential circuits and amounts to $\frac{1}{2}$ to 1 ampere.

Having generally described the different cases of motor regulation, let us take up the mathematical relations, current, speed and load, which may be expressed quite simply.

Using the symbols P C S and L as defined above, we have $P \times C$ as the total electrical energy supplied to motor in watts, or $\frac{P C}{746}$ in horse-power. Calling commercial efficiency a, the actual mechanical horse-power developed by a motor is $\frac{a P C}{746}$ expressed in electrical terms. The equivalent expression in mechanical terms is $\frac{2 \pi S L}{33000}$. Since the point at which load L is measured is 1ft. from centre of shaft and travels 2π feet per revolution, or $2 \pi S$ feet per minute, this, multiplied by the load and divided by 33,000, gives the horse-power developed by the motor.

Thus we have:—

$$\frac{a P C}{746} = \frac{2 \pi S L}{33000} = \text{horse-power of motor;}$$

or,

$$P C = \frac{746 \times 2 \pi S L}{33000 \times a} = \frac{S L}{7 \cdot 04 \times a}$$

For convenience we may write $P C = \frac{S L}{7 a}$ with an error of about one-half of one per cent.

If the efficiency a of motor is 85·2 per cent., the denominator, or 04 a, becomes 6 exactly, and we have $P C = \frac{S L}{6}$; and if the efficiency is 75·8 per cent. we have $P C = \frac{S L}{5}$. The former is as high and the latter is as low as is ordinarily met with in practical work; therefore these are the limiting values.

The equation $P C = \frac{S L}{7 \cdot 04 a}$, or one of the three simplified forms just given, may be advantageously used for solving problems in motor regulation. If we know any four of the quantities we may, of course, find the fifth by simply solving the equation with respect to it. It is also evident that if any three of the quantities are constant then the other two will vary directly or inversely with each other, depending upon their position in the equation. This is the ordinary case we have to deal with in regulation. Usually speed is required to be constant, either potential or current is maintained constant, and efficiency should be practically constant down to very small loads; thus we have either current or potential or load varying directly with load. The efficiency is rather a confusing element in motor regulation. For this reason it was not introduced as a fifth quantity in the second table, as it would have complicated it and made a great many more possible cases. The efficiency should be high (close to 100 per cent.) and as nearly as possible constant, therefore it would not affect the figures much.

If the load or speed is zero, or very low, the potential or current should be correspondingly reduced, and the efficiency would remain constant. This is the condition for perfect regulation. Practically it always takes some current to overcome friction, &c., even when load is zero, in which case efficiency is zero; but this current should be very small.

The equation $P C = \frac{S L}{7 \cdot 04 a}$, applied to the cases marked "not practical" in second table, shows in Case 4, for example, that if P C and L are constant, the efficiency a decreases directly with reduction in speed. This is not allowable. The same is true of the other cases, and shows that it is not proper to vary P C L simply at the expense of efficiency, or, in other words, waste current to obtain regulation.

Having now given the general points of motor regulation, we will consider the forms of motors which are now being used extensively.

First, and most important, we have the regular shunt motor for constant-potential circuit, which has already been referred to several times. Thousands of this type of motor are in use, and give very satisfactory results. A properly designed motor of this kind will regulate within 5 per cent., which is near enough for most purposes. It has no regulating mechanism or complicated circuits to get out of order, and it may be called the ideal self-regulating machine. The next important form is the differential-wound motor, which is even more perfect in closeness of regulation, theoretically, and it might be made almost absolutely constant in speed; practically the speed varies about 2 per cent.

These are the figures given me by the company who manufacture these machines in the largest quantity and of the most excellent workmanship. Sylvanus Thompson gives an example of one of these machines, which only varied $\frac{1}{2}$ per cent. in speed with a variation from 1·1 to 11·14 horse-power.

The rule for winding differential motors is that the number of turns in the shunt divided by the number of turns in the series coil are equal to the resistance of the shunt divided by the resistance of the armature plus the resistance of the series coil. On this side of the Atlantic this is called Sprague's law of winding; on the other side it is called Ayrton and Perry's rule for winding. The slight variation in speed which does occur is due to the heating of the two coils and other slight disturbances. This shunt coil varies considerably in resistance effected by heating; therefore the series coil should have a few less turns than the rule requires. The heating of the shunt coil weakens the current in it, and consequently the field magnetism, thus increasing the speed of the machine; therefore the motor runs faster after it has been running for some time. The proper way is, of course, to consider the true speed to be that which the motor has in steady running. At first some trouble was experienced in this type of machine on account of short-circuiting between the series and shunt coils, but this has been overcome by more perfect insulation.

The shunt or differentially-wound machines may be varied in speed by putting resistance in the field circuits, as shown in Fig. 1. This may, of course, be done automatically or by hand, usually the latter.

The next important type of machine is the constant-current motor. As already stated, this is merely a series-wound machine, with switch for cutting in and out the field-coils, the latter being operated by an automatic centrifugal governor, as indicated in Fig. 3, or by hand. Various modifications of this type have been made—for example, a reversed coil may be wound on the field-magnet coil and having a variable resistance in circuit with it. If this resistance is very high, the reversed coil has little or no effect. If this resistance is made very low it will rob the main coil of its current, and also neutralise its effect, thereby greatly reducing the strength of the field-magnet. All these motors with varying field strength have the drawback that a certain time is required for the magnetism to vary, and the regulation is therefore sluggish. If we

Digitized by Google

attempt to hasten this by laminating the field-core we have sparking at switch points, due to self-induction in field-coils.

Constant-current machines with regulator are now in great demand for arc circuits; in fact, it is not practical or safe to use a motor on an arc circuit without a regulator, as the danger of racing away is very great.

The differential winding of constant-current motors to maintain constant speed is not practicable. The solution of it requires either that the efficiency should be very low or that storage batteries be used in connection with the motor to maintain a constant difference of potential. Any such plan as this is, of course, very objectionable.

The three types just given are really about the only continuous-current motors used to any extent in practice, and it seems that there is at present no demand for any other type.

Nothing has been said of the regulation of alternating-current motors, because it is a radically different subject, and, moreover, alternating-current motors tend to run synchronously, maintaining a constant speed and regulating themselves.

In conclusion, I would say that I would like to see this subject taken up by leaders in electrical science.

RELATION BETWEEN THE INITIAL AND AVERAGE EFFICIENCY OF INCANDESCENT LAMPS.*

At the recent meeting of the American Institute of Electrical Engineers an able Paper upon the above subject was read by Mr. W. H. Peirce, who has carried out a careful and elaborate investigation into this question on behalf of the Chicago, Burlington and Quincy Railroad Company. We regret that the space at our disposal will not permit us to give Mr. Peirce's Paper at full length, together with the numerous diagrams which accompany it. Fortunately, however, the final result arrived at is adequately presented in the four diagrams which we reproduce on an enlarged scale. Mr. Peirce commences with the remark that "At the present day there is very little reliable published information relative to the variation with age of the economy and light-giving power of incandescent lamps." The methods adopted in making the electrical and photometrical measurements and required tests are fully described in the Paper, and we think there can be little doubt as to their suitability or as to the care and skill with which the tests were carried out.

Measurements of candle-power and efficiency were repeated for each of 94 lamps (supplied by four different makers) after a life of 55, 110, 200, 300, 400, 500, 600, and 800 hours respectively. The results are embodied in the subjoined diagrams and tables, which are explained by Mr. Peirce in the following terms:—

"In the accompanying curves each make of lamp is designated by a letter. A_1, B_1, C_1, and D_1 have reference to the purchased lamps; A_2, C_2, D_2 indicate those tested at the request of the lamp companies. In either case similar letters refer to like make of lamps.

"In the first of these (Plate 1) is shown the variation with age in the economy and candle-power of all the lamps. Each curve represents a batch of from 10 to 15 lamps; thus the C_1 lines relate to the 15 lamps purchased, and the C_2 curves indicate the influence of life upon the lamps contributed by the *C* lamp company.

"The upper set of curves illustrate the economy of the several lamps at their different periods of life. Thus the A_1 curve indicates that these 15 A lamps when new consumed 3·54 watts per mean horizontal candle, that after 900 hours 6·1 watts of electrical energy were necessary to produce one candle-power of light, and further that during 900 hours the mean economy of the lamps was 5·25 watts per candle-power.

"The lower diagram indicates the effect of age upon the light-giving power of the lamps. Thus the A_1 curve demonstrates that these A lamps after 900 hours gave but 58½ per cent. of the initial candle-power, and that the mean intensity of light during 900 hours was 67 per cent. of the new lamps. . . . .

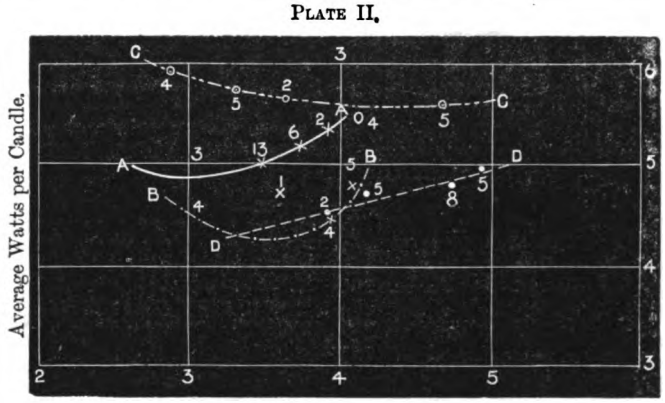
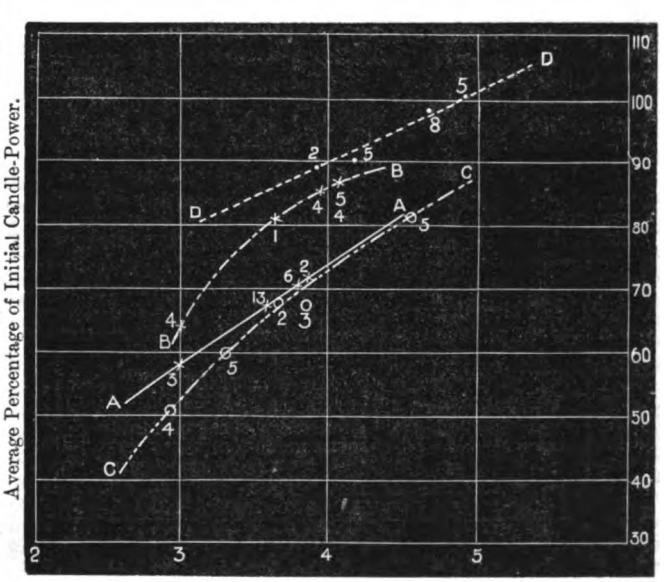
PLATE II.





Digitized by Google

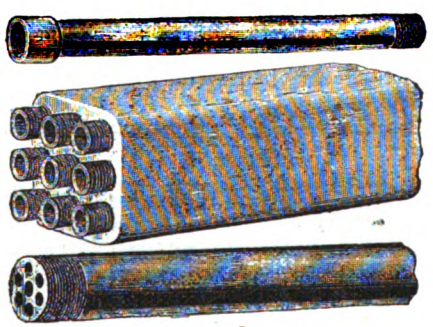
"In the second series (Plate II.), we have a summation of all previous diagrams and tables. These curves show the relation between the initial and average efficiency of the incandescent electric lamps studied. These curves are plotted with the initial economy of the lamps as abscissæ, and the corresponding averages deduced from the preceding curves as ordinates. The figures at the plotted points have reference to the number of lamps used in determining each point.

"From these curves we learn that the varying of the initial economy between the limits of 3 and 5 watts per candle does not greatly affect the average economy, but it does have a very marked effect upon the average candle-power derived from the lamp."

THE MEDBERY UNDERGROUND SYSTEM.*

Undoubtedly the most serious problem that is agitating the minds of electricians at the present time is that of laying electric light and power distribution wires underground in a safe, economical and durable manner.

Many systems and plans have been devised to accomplish this result, and while many of them are meritorious and deserving of attention, nothing has been found that successfully accomplishes the desired results. The chief difficulty has been the inability to guard the wires properly from contact with the conduit or from gases and moisture. It has also been found difficult to provide a system that will protect human life without great and expensive outlay. An ideal system, moreover, must combine extreme durability with ease of laying and distributing for house and street lighting and power.



Figs. 1, 2 and 3.—The Medbery Underground System.

The system which we now call attention to consists of one or more tubes made from wood fibre and treated with a chemical compound which renders it water and fireproof. The material is not subject to deterioration by the action of acids or gases, but is of great strength, practically indestructible, and not subject to decay when placed underground. The sections are joined by threads cut in the pipe, like iron pipe, and with a sleeve coupling. At the manholes the pipes do not terminate as in other subways, but continue directly through with a collar which can be unscrewed when necessary to reach the cables or wires. Hence gases and moisture cannot get into the pipes. For all underground wires this advantage is of great value, as explosions cannot occur as they have done with existing methods and material. This system is especially desirable for telegraph and telephone wires, and is highly commended by several of the largest corporations in the country.

The conduit for light and power wires and system of distribution, which is shown in perspective in Figs. 1, 2, and 3, combines several new and valuable features. Each "conduit" is divided into four or more compartments, made of a perfect insulating material, and the wires occupy separate ducts, which precludes the possibility of "cross arcs"; and in the event of a "misplaced" switch at the station, and the "positive" current being turned into the "negative" conduit, no harm nor damage can ensue. The question of the cost of properly insulating wires is one of considerable importance. The expenditure is necessarily very great in the ordinary method of laying wires; but in this conduit, by reason of its high insulating qualities, expensive insulation of wires is avoided.

Another noteworthy feature of this system is the method of distributing to houses and street lamps. Usually it is necessary to make provision for this when laying the conduit, which is necessarily very expensive; but by this system side taps and connections can be as easily made *at any time* after the conduit is laid, and without serious expense, as will be seen from the accompanying illustrations, Fig. 4 and 5.

* From the *Electrical World* of New York.

When desiring to make connection with the main line, the conduit is exposed at any point, and an opening is cut in it in any preferred manner. It is usually drilled. The wire is then lifted from its resting place in the conduit, through the hole in the conduit, and the two parts of the metallic clamp G being first separated are put over the wire and firmly attached thereto by means of a screw. The clamp has a chamber into which a suitable metal or solder is melted or fused, making a perfect contact and permanent joint. The two sides of the casing or connecting box (which, it will be seen, has a recess or hollow interior) may be filled with suitable insulating cement while in a plastic state, and they are then placed about the conduit in such a manner that the extension of the clamp H projects through the neck of the casing, as shown in the cut. The bolts are then inserted in the lips of distributing duct B, and screwed up. The cap C is then applied and forced firmly down upon the tapering neck of the casing, after being properly cemented.

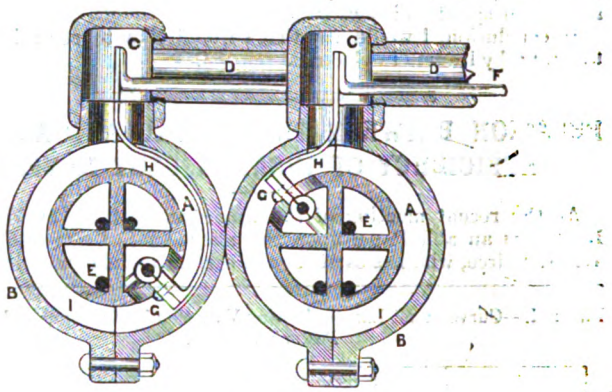


Fig. 4.

The branch wire is then connected with the extension from the clamp H, and when it has been passed through the first length of the branch conduit F, the branch conduit is screwed into the threaded hole in the side of the cap C, or preferably cemented into place. The branch line can thus be extended as far as may be desired. Thus far in the process connection has been made with one wire only, either the negative or the positive wire; but, of course, the connection with the other wire will be made in a similar manner.

After both connections are made and all parts are secured in place, the entire device is enclosed in a mass or ball of hydraulic cement, as indicated in Fig. 2, which will solidify and protect the parts from accident or injury from tools of workmen in subsequent excavations.

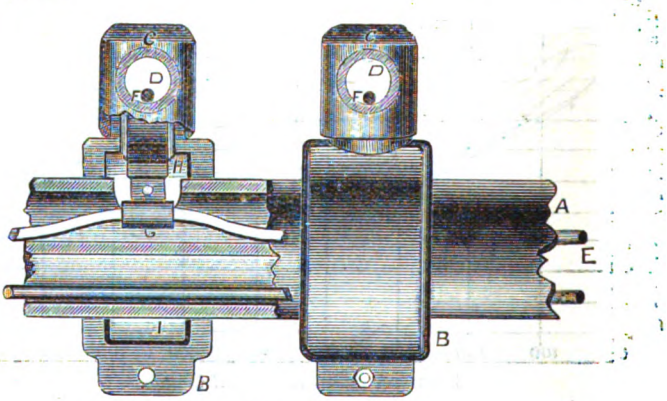

Fig. 5.

The advantages of this system over any other are apparent, as the main conduct can be opened at any time, and connection made in a very easy, expeditious and inexpensive manner, and is not restricted to any defined place, as under the old method. This is a matter of great importance in cities where gas, sewer, water, and other pipes or conduits frequently interfere with, if not preclude, access to the conduit at the points where the connection boxes should happen to be located.

The system as above outlined is being introduced by the American Indurated Fibre Company, of Mechanicville, N.Y. It may be mentioned that satisfactory practical work with it has been done by the Bell Telephone Company, of Philadelphia; the Pennsylvania Railroad Company, and others.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 8, 1889.

During the present week the financial and speculative world of New York has practically been in a state of suspended animation, owing to the absolute and complete cutting off of the "ticker" service from the floor of the Stock Exchange by the Governing Committee of that body. The action was taken very suddenly, and does not appear to have been expected up to the 1st inst., when the contracts of the Stock Exchange with the Gold and Stock Telegraph Company and the Commercial Telegram Company expired. It seems to have been generally supposed that those contracts would have been renewed, but at the last moment the Committee determined to discontinue the ticker service without warning, and it did so, although it had made no provision for resumption or for the substitution of any other service that would be equally expeditious and efficient. The main object of this action on the part of the Governing Committee was to deprive the "bucket shops" of their quotations. There have been various rulings from time to time on the question whether the quotations, as made on the floor of the Exchange, belong exclusively to that body or are public property, and the result of the litigation has been that the Exchange has been required not to discriminate between the rival ticker companies, and that the ticker companies in turn have been required not to discriminate between their customers; so that as long as the Stock Exchange allowed the quotations to go out over the ticker wires the "bucket-shop" proprietors obtained them just as freely and as fully as anybody else. Now, it might seem to be a little below the dignity of so large and wealthy and powerful a body as the New York Stock Exchange to take such extreme measures against people whose business has been more than once stopped by the officers of the law as gambling of an illegal and pernicious nature; but to the Committee and to most of the brokers there appeared to be no other way out of the difficulty, and from time to time the advisability of keeping back the quotations altogether has been very seriously discussed at the Stock Exchange, for the reason that, however small and mean as opponents, the bucket shops individually might be, the amount of business done by them is in the aggregate enormous, and has the effect of diverting from the Exchange a great many orders that would otherwise find their way there. It is estimated that there are throughout the country about 5,000 bucket shops, where, daily, clerks and messenger boys and humble men with very small means, gamble in small lots of shares at correspondingly small risks. If each of the bucket shops averages 200 shares a day, their total business each day would amount to one million shares of stock, and in all probability it rises to a much higher figure than that. It appears that for the four full business days of last week the average sales on the Stock Exchange amounted only to 387,540 shares. From these statistics it may be gathered that the diversion of business was by no means insignificant. Another reason for the smallness of the business lately done on the Stock Exchange is the fact that a younger body, known as the Consolidated Exchange, has lately extended its operations from oil and mines to telegraphs and railroads and the other securities dealt in on the Stock Exchange, and this again has served to cut down patronage enjoyed by the brokers of the older and more conservative body. It is claimed by the Governing Committee of the Stock Exchange that their action in silencing the tickers was aimed solely at the bucket shops, but it is not unlikely that the Committee may also have had the Consolidated Exchange in view. Anyhow, the blow was struck, and on the Stock Exchange the brokers, in default of any substitute for the ticker service, had to fall back on the telephone and the old method, known as "pushing the pad," which consists in scribbling the quotations on a pad as fast as a sale is made on the Exchange, and sending off the slip at once by messenger; but while the brokers have been restricted to these crude devices, and have been grumbling at it in a resigned sort of way, the bucket shops, while at first they staggered under the blow, have "bobbed up serenely," and now seem to be doing as much business as ever. In several of the bucket shops this week the tickers have been reeling off their quotations on the tape in the familiar manner, and, as far as could be ascertained, the prices were pretty nearly correct. At the Consolidated Exchange the brokers began making their prices independently of whatever business might be done on the Stock Exchange, and it is asserted that the experiment has proved a success. The Consolidated Exchange has, moreover, a separate ticker service of its own operated by the Stock Quotation Company, which, owing to the crippled condition of its competitors, the Gold and Stock and the Commercial Telegram Companies, has been doing a rushing business.

While this action of the Stock Exchange has caused a tremendous sensation, it cannot it appears be considered altogether a success, and there are rumours already that the Exchange has in view the establishment of yet another ticker system of its own. There appears to be some foundation for the report, but the matter is kept extremely secret, and nobody knows just what the new system is likely to be. The fact that the Governing Committee already finds it necessary to promise some substitute of this kind shows how imperative is the necessity for the ticker service. In view of the magnitude of the public interest involved in the quotations made on the floor of the Exchange, the public and the Courts have been slow to recognise that the Exchange has any vested and exclusive right in such quotations; and it stands to reason that those who are interested in the movements of the Stock Market, as hundreds and thousands are every day, to say nothing of those bent on speculation, will find it impossible to make the laborious journey to the nearest broker's office whenever they wish to ascertain the current price of some of the stocks. In fact it is out of the question that such people should make long journeys to offices in the neighbourhood of the Exchange, and it is also evident that unless they do so, so long as mere memorandum pads are used, supplemented by slow-footed messengers, the offices nearest the Exchange would have a vast and unfair advantage over those which happened to be a little further removed. The ticker service equalised all these conditions, and its resumption on as large a scale as ever may be early expected. The same may be said of other cities like Chicago, where similarly abrupt and extreme action has been taken. In Chicago, in connection with the dealings in grain, several of the commission men reported that some of their customers who could not secure continuous quotations said that they will not trade at all unless they can be furnished with them, so that the action of the authorities is already developing some unpleasant boomerang characteristics.

You will remember that a few weeks ago I described in this letter the Williams "portelectric" system of transportation, the *modus operandi* of which consists in sucking a carriage through a succession of electro-magnetic helices mounted on posts and girders, like an elevated railroad. The system was exhibited in New York for a time, and is now being shown in Boston, where its ingenuity is attracting a great deal of attention. At this stage, however, Dr. Henry Wurtz, a well-known chemist, comes forward with a letter in the *Engineering and Mining Journal*, making claims to have devised a similar system as far back as 1860, at which time, being then an examiner in the Patent Office and not entitled to take out patents, he placed his Paper in the hands of Prof. Joseph Henry, at the Smithsonian Institution. His apparatus he proposed at that time to call the electro-magnetic tachyphore. Prof. Henry, Dr. Wurtz states, regarded the invention as then highly premature, and as one which was scarcely likely to be valuable in our day, both because there was not an adequate source of current and because the public had not grown up to the necessity for such a method of transportation. Dr. Wurtz states that at a later date, when no longer in the Patent Office, he recurred to the subject, and then became aware of the existence of two prior British patents, Nos. 58 and 514 of 1862, one issued to Bonelli and the other to H. W. Cook. Both these patents, it is true, like Dr. Wurtz's idea, seemed to come tolerably near the main device or principle, although Bonelli's feature of carrying a battery on the vehicle would seem to present insuperable objec-

Digitized by Google

tions. Here, then, we have another of the anticipations which beset the ingenious and aspiring inventor of to-day, and the question once more arises how far these anticipations, which amounted to nothing and never did anybody any good, should be allowed to stand in the way, and operate to the detriment of the later inventor, who, seeing the necessity of the times, has brains and energy enough to carry the idea to completion and perfection. I do not now propose to discuss the relative merits of the inventions of nearly thirty years ago, and of that which Mr. Williams is now introducing to public notice as the portelectric system. I have no doubt that there are many features in Mr. Williams' system peculiar to it, and upon which he has good patents; and if there be anything of merit in his invention by means of which the transportation of mail matter and the parcel delivery can be expedited, I for one should be very glad to see it successfully exploited.

A very interesting statement has been published this week as to the cost of operating electric railroads in this country. The tests in question have been made on the Daft-road, using the overhead system at Asbury Park, one of our popular seaside resorts in New Jersey, and were carried out by Mr. F. E. Idell. At the time that the tests were made, there were 14 cars running on the road. The conditions were by no means favourable to the showing of high economy. There were, for example, three engines of a total 180 horse-power, developing a maximum of 120 horse-power, while the average horse-power for the two days' run was less than one-half their normal rating. Of course the economy could not be as great as if they had been running on full load. Another point was that the steam-piping was large enough to supply double the engine capacity, and that it was, moreover, uncovered. In spite of such material drawbacks as these, Mr. Idell determined that at the place named the cost of motive power for operating the 14 cars from 17 to 18 hours per day is $3.13 per car, which, of course, would be considerably reduced if the number of cars were increased. The figure that I have given includes interest and depreciation on cost of the power plant, the overhead system and the motors, the wages of the two engineers and two firemen, coal, oil, waste and water. If the number of cars were increased to 20, the cost of the motive power would fall to about $2.68 per day. Now, when operating the 14 cars by animal power, at least 140 to 200 horses would be necessary, and the average cost of keeping these in this country would be 50 cents a day, or a cost of $5 per day for a car, to which must be added the interest on the investment in the horses themselves and in huge stables, running the figure up to at least $6 per day per car. This, of course, is taking the road under normal conditions of active operation. In winter the advantage is still more in favour of the electric road, as the output of power is then strictly proportionate to the lessened work being done, whereas if animal power were used the horses would have to be sold at a great reduction, or else kept all winter eating their heads off. Then, when the summer came round again, if they had been sold new stock would have to be bought at a high price. Mr. Idell's Paper did not include any electrical measurements, but simply took the cost of delivering the current to the motors, but that is enough, as a general thing, to satisfy railway managers inquiring into the subject.

I need hardly go into details regarding the awful disaster at Johnstown, Pennsylvania, last week, as by this time every newspaper in the civilised world has contained some account of the manner in which the Conemaugh Lake burst its banks and swept down the narrow valley, destroying towns and hamlets, and drowning thousands of the industrious inhabitants. The incident has caused a most painful sensation throughout the country, and every community is hastening to mitigate the horrors of the occasion by contributing freely to the various relief funds that have been started. One of the striking features of the incident was the suddenness with which unfortunate Johnstown was cut off from communication with the outer world. The manager of the local Western Union Company was a lady, Mrs. H. M. Ogle, who died at her post in a most heroic manner. In spite of repeated notifications that she must get out of reach of danger, and at a time when the swollen waters were already beginning to rise rapidly, she refused to leave the instruments, and went on sending warnings down the valley. When every office in the path of the coming current had been warned the huge wave was upon her, and with her sad words, "This is my last message," all communication between Johnstown and the outer world ceased. This is an example of heroism which matches that of the little telephone girl who kept at her post at Jacksonville, Florida, all through the last yellow fever epidemic, and by her work did much to assist in saving the sick and burying the dead. Reports from Johnstown show, as your readers are doubtless aware, that the whole city has practically been wiped out of existence. The telephone exchange and the telegraph office have gone, and nothing remains of the fine Edison plant of 5,000 lights which had been in operation successfully for three or four years.

Since I wrote the first part of my letter, two or three days ago, there have been further interesting developments in the ticker matter, with the result that the voice of the ticker is heard in the land once more. So far as can be gathered from what has been made public, the Stock Exchange policy has led to an understanding between the two regular quotation companies, which hereafter are to work in harmony. The instruments of the Gold and Stock Telegraph Company are to be supplied to regular members of the Exchange, while the general public will be furnished with the instruments of the Commercial Telegram Company, which, it is said, will send out its quotations one or two minutes after those of the Gold and Stock Company, so that while the public will still get its information, it will have to go to the office of a regular member of the Stock Exchange if it wishes to get that news promptly. Moreover the rent of the instruments is to be advanced from $10 a month to $25, and the instruments of the Commercial Company will only be furnished to persons of whom the Stock Exchange approves. In such way, it is believed, fondly but foolishly, that bucket shops will be prevented from obtaining their quotations. It is popularly rumoured that this arrangement would not have been effected if Mr. Gould had not threatened to cut the Stock Exchange off absolutely from all telegraphic communication whatsoever. Prominent officers of the Stock Exchange deny this story very emphatically, as they do also the statement made as to the arrangement, but their denials may be taken largely in a diplomatic sense. As to the effect on the bucket-shops, it is perfectly safe to say that under this new arrangement they will have their quotations just as soon as anybody, and much sooner than those who are dependent on the service of the Commercial Telegram Company. How this arrangement, moreover, is likely to suit the Commercial Telegram Company it is not easy to see. They may find a salve for their wounded pride in a steady and assured income at the higher rates, but hitherto it has been their boast, and with some show of reason, that they could whip the Gold and Stock Company out of their boots. Perhaps they may consider their end gained when Mr. Gould thus admits them to partnership.

BERLIN NOTES.

(FROM OUR OWN CORRESPONDENT.)

June 16, 1889.

The Electrical Section of the Berlin Safety Appliance Exhibition cannot be said to represent the present state of the industry in Germany, as many leading firms are not exhibiting at all, while others show but a small part of the apparatus they specially manufacture.

The Deutsche Elektricitäts Werke (Garbe, Lahmeyer and Co.), of Aachen, represented by the firm of Erfurth and Sniell, Berlin, exhibit two dynamo machines of the well-known Lahmeyer type, driven by belting from a Westinghouse engine. This plant, which is placed in the Machinery Hall, exhibits Herr Lahmeyer's interesting distributing system in action. The main dynamo machine, which is compound-wound for 270 amperes and 110 volts, is connected in series with a small series-wound regulating dynamo machine, which gives an E.M.F. of 24 volts. The system, which has been described in *The Electrician*, is already being used in a central station at Bostock, where the regulation is found to be exceedingly perfect; but the details of construction of the machines and switch-board are not sufficiently novel to merit special description.

Digitized by Google

Amongst machinery not in motion, Herr Schuckert, of Nurnberg, exhibits a dynamo coupled direct on to an engine of the type produced by Herren K. and T. Möller, Brackmede, and standing on the same bed-plate. At the high pressure used for marine engines, the plant being specially designed for ship work, the engine gives 16 horse-power; it has two cylinders, which makes it run exceedingly smoothly, and is considered a distinct advance on the central-valve engines hitherto made. Owing to the small weight and space occupied by this plant, as compared with its capacity, the requirements of the navy are fully met by it.

The dynamo machine is shunt-wound; the field-magnets consist of a vertical cast-iron ring, with eight poles pointing radially towards the armature, which is of the drum type, having an output of 150 amperes and 70 volts when running at 550 revolutions per minute. There are twenty-four connections to the commutator, every four bars of which, at an angular distance from one another of 90deg., are coupled in parallel, so as to require only two brushes, which, however, for practical reasons are separated by 135deg. instead of 45deg. On the switch-board are a rheostat for the dynamo, a strong double-pole switch, a voltmeter, and an ammeter specially designed by Hummel for use on shipboard. The weight of the engine and dynamo together is 1,700 kilos., that of the dynamo alone 830 kilos. The weight of copper on the armature is only 14 kilos., and of that on the field magnets 88·5 kilos.

The most interesting part of Herr Schuckert's exhibit consists of his projector lamps—one designed to work with 60, another with 150 amperes. A great number of these projectors have been supplied to the home and foreign armies and navies, and are claimed to be the best yet constructed. An electric motor gives the projector its movement in both the vertical and horizontal planes by moving a switch. The vertical motion is limited, but the projector can be swung right round in the horizontal plane, the current passing through strong circular contact springs. The arc can be placed in the exact focus of the parabolic reflector by the aid of a piece of silvered glass with scale, and is kept in position by means of an electro-magnetic contrivance, so as to prevent ascending currents of air carrying it against the upper carbon, and causing it to burn away irregularly. The parabolic mirror is said to be the most perfect yet constructed, for although 960 millimetres in diameter, it is of uniform thickness throughout. The method of manufacture of these reflectors is patented by Herr Schuckert. To stop vibration, the reflector is mounted on an iron frame covered with layers of asbestos, and held in position by a number of smooth copper springs. In the front of the lamp case is placed a disperser, by means of which the rays of the lamp can be made parallel, or dispersed horizontally, so as to make a beam of light, whose angular breadth is 45deg. The opening of the lamp is ordinarily protected by means of glass strips of suitable breadth, but it may also be entirely closed by the addition of a venetian blind arrangement if a signalling light is required. The arc is regulated by two electro-magnets, one of which strikes the arc, the other, placed in shunt with the main current, controls the movement of the carbons.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *June* 12, 1889.

Ischl, the well-known beautiful health resort in the Salzkammergut, is now to have the electric light. The Town Council have bought the Traunmill, which they propose using as the motive-power for the proposed installation, the water-power being very considerable.

Trient will be lighted entirely with electricity by the end of this year. The motive-power will be water, 600 horse-power being available for the purpose.

The lighting will be done almost entirely by glow lamps. The price proposed is 50 kreutzers a year per candle-power. In order to show the citizens the advantages of the electric light and of electricity as a motive-power, the Town Council have opened an Exhibition showing the use of the electric light in every form, in the house of the rich and in the cottage of the working man, also the use of the electric current for driving machinery in a private house and in the workshop. Over 1,000 lamps have already been subscribed for by the inhabitants.

The electric installation in Marienbad will be opened this week, as already reported. This installation has been carried out by Messrs. Ganz and Co.

The shares of the International Electric Company, promoted, as reported, by Messrs. Ganz and Co. and the Union Bank, have been issued. The issue was a great success. The company's capital is 3,000,000fl., or about £250,000, divided into 15,000 shares of 200fl. each. They were issued at 240fl., or 20 per cent. premium; 300 were reserved for the directors, 4,800 for Messrs. Ganz and Co., so that 9,900 were issued. These were over-subscribed for nearly *a thousand* times in Vienna, Frankfort, or Budapest. For years nobody would subscribe anything to electric or telephone companies in Austria; now suddenly the mania seems to have bitten Continental or rather Austrian capitalists, and they have subscribed to a company which, up *to date*, has really only a few patents to work on. There is, however, a great field open for electric enterprise in Austria, and English capitalists would do well to try and share the field. Austria is a country capable of infinite development, having very little capital, and much can be done here by judiciously investing capital and with honest work.

The Union Bank has also undertaken the issue of the new capital of the Vienna Telephone Company. This will also be issued at a premium, and amounts to nearly £150,000. The number of subscribers in Vienna is increasing rapidly; cables are being laid for 3,000 more. In the large provincial towns much activity prevails. These belong to the Telephone Company of Austria. The number in these worked by this company now amounts to over 2,600. Over 60 stations and lines are given by the company, free of any charge, to the fire brigades, hospitals, and other charitable institutions.

The telephone is largely used in Austria by the fire brigades, especially by the volunteer fire brigades in the smaller towns. In Bielig, for instance, a large bell has been put up in the company's tower. As soon as a fire is reported to the telephone central station, the head officer of the fire brigade is called, and the bell rung by turning a switch, thus calling together the members of the volunteer fire brigade. The company's system of lightning arrestors has proved itself very good.

The thunderstorms this year have been terrific. On May 21 a great storm took place in Richenberg, and many houses and factories were damaged, but not one where the telephone wires crossed, and it is believed that they must have prevented much damage. For a long time the central station was not put to earth in order to enable any fire reports to reach the fire brigade; three such reports were received, and the speed with which the messages were delivered and the fire brigade appeared prevented the fire taking hold.

In the end, however, it was impossible to work any longer, all drops falling together, and the office had to be grounded. In spite of this storm only comparatively little damage was done. Out of 330 stations only about 20 coils were burnt and about 22 drops injured.

COMPANIES' MEETINGS & REPORTS.

Submarine Telegraph Company.

An extraordinary general meeting of the Submarine Telegraph Company between Great Britain and the Continent of Europe (Limited) was held at the offices, Throgmorton-avenue, London-wall, on the 19th inst. The chair was occupied by Sir Julian Goldsmid, Bart., M.P.

The SECRETARY (Mr. S. M. Clare) read the notice convening the meeting.

The CHAIRMAN: I have very little to say to you to-day. I informed you last time that we had to call these two meetings in order to satisfy the requirements of the solicitor of the Post Office. I think that when we have completed this meeting to-day we shall have done all they have demanded of us, and that therefore, as far as they are concerned, we shall be able to finish all the arrangements we have to make with them. You all know probably that we have realised the reserve fund, and that that realisation has already produced a distribution of assets among the shareholders, as you have received your warrants for 75 per cent. of the capital of the Company. The realisation of the reserve fund has been a satisfactory one. I think it shows that we made fair investments on behalf of the Company, because those investments have realised about £28,000 more than they originally cost us, and consequently in that respect I think we can have no complaint to make. We have further to receive now, as soon as the Post Office is ready to pay us, the sums they have to pay for the purchase of the cable, for this house, and so on, and we have also to receive the money from the Paris and New York Company which they have to pay us for our half share in the Deolen cable. Then, subsequently, we shall have only one more matter to complete—that is, to come to some arrangement with the Anglo-American Company as to the Salcombe cable. That, I am afraid, will be the longest matter we shall have to deal with, and it will, therefore, delay the final realisation of the assets of the Company. We shall, however, do all we can to press forward a settlement, but you will understand that when these other bodies are concerned matters do not depend on us. I shall be ready to give you any further information I can, but meantime the motion I have to propose is as follows:—

"*That the Company be wound up voluntarily, under the Companies' Acts, 1862 and 1867, and that Sir Julian Goldsmid, Bart., M.P. (the Chairman of the Company), the Hon. Henry Robert Brand (one of the Directors), and Mr. Stephen McDonnell Clare (the Secretary), be and they are hereby appointed liquidators for the purpose of such winding up.*"

I have to propose that as a confirmation of the resolution passed at the previous meeting.

The Hon. ASHLEY PONSONBY seconded the motion.

Digitized by Google

The CHAIRMAN put the resolution in the usual way, and said: No poll is demanded, and I declare the resolution carried. Continuing, he said: It was discussed at the first meeting we held some time ago on the subject of the liquidation what payment should be made to the liquidators, and I then stated that I thought the best plan would be for their remuneration to be settled at the final meeting. If you approve of that suggestion, it would be well that you should pass a resolution to that effect. Perhaps Mr. Carmichael will move it.

Mr. CARMICHAEL: I will move

"*That the remuneration of the liquidators be settled when they present the account of the liquidation.*"

Mr. KING seconded the motion, and expressed the hope that the expenses of the liquidation would be made to fall as lightly as possible upon the shareholders—he referred to the payment to be made to Sir Julian Goldsmid and his co-liquidator. As a matter of pay for services rendered, the sum might be a substantial amount; but he thought he need hardly appeal to those gentlemen, in the circumstances of the case, to make the expenses as light as possible, as it would be a kind and gracious act to do so. His remarks did not apply to Mr. Clare, the secretary, who, as they knew, was the person upon whom, in such matters as these, the weight and burden of what had to be done would fall. He had made the suggestion in the interest of many lady shareholders. He felt that an uncommonly shabby settlement had been imposed on the Company by the Government, who were acquiring a magnificent property from those who had had the enterprise to initiate it. He thought that the country in the end might find that the Government had overstepped the mark, as such proceedings were precedents; but in the meantime the shareholders had no redress. They were at the mercy of the Government, who had chosen to squeeze them most unmercifully.

A SHAREHOLDER inquired if the Company would participate in the earnings of the first three months of the current year?

The CHAIRMAN: I am quite sure that neither Mr. Brand, nor Mr. Clare nor myself would wish any undue payment to be made for any work we do with respect to the liquidation, but I do not think it would be fair or right that it should be done without remuneration. It is the regular practice in these matters, but we shall not ask for anything unreasonable. I stated at the first meeting that among the assets for the liquidation would be the proceeds of our share of the earnings for the three months ended March 31 last. These accounts are now being prepared, but they have to be submitted to a variety of persons. He then put the motion, which was carried.

A SHAREHOLDER: What do you suppose the shareholders will receive, leaving out of consideration the matter to be arranged with the Anglo-American Company?

The CHAIRMAN: I told the last meeting that we should give them something over par. That amount will be something between 105 and 110; but I cannot say definitely, until we settle with reference to the Salcombe cable and as to the expense in the preparation of the accounts of the liquidation and a variety of other matters. In answer to other questions, he added: I told the shareholders at the last meeting that I hoped within a fortnight or three weeks that we should distribute a great part of the assets of the Company. We have already done so, in anticipation of this meeting. We posted 75 per cent. to the shareholders yesterday, and that money will be paid forthwith. As soon as we have the money in hand to justify our paying a further considerable amount we shall do so. I have been pressing Mr. Clare from day to day to push forward this matter. It does not, however, depend on him alone, but on the Government, who have to pay us, and on other persons. I am certain we shall be only too glad to give you as much more as we can on account, and the final payment will depend on the closing of the accounts. These premises have been valued by a competent valuer appointed by the Government and ourselves. The Government thought he had put them too high, and we said he had them too low; but if you ask me for my independent judgment, I should say he fixed a fair value.

Mr. KING then proposed a vote of thanks to the Directors for the way in which they had administered the affairs of the Company for so many years, and expressed regret that such service must now end.

The motion having been seconded and adopted,

The CHAIRMAN briefly replied, and the meeting then separated.

German Union Telegraph and Trust Company, Limited. (*In Liquidation.*)

A general meeting of the members of this Company was held at Winchester House, 50, Old Broad-street, on the 17th inst., "for the purpose of having the liquidators' accounts, showing the manner in which the winding up has been conducted and the property of the Company disposed of, laid before them, and of hearing any explanation that may be given by the liquidators; and also to determine by extraordinary resolution the manner in which the books, accounts, and documents of the Company, and of the liquidators thereof, shall be disposed of." The chair was occupied by Sir James Anderson.

Mr. WILLIAM PAYTON read the notice convening the meeting.

The CHAIRMAN: Gentlemen, before moving the resolutions I will just make one or two observations. Naturally the shareholders are disappointed at not receiving a larger sum of money for their shares, or such sum as we held forth as probable a year ago; but the irony of fate has been very hard upon us—so much so that since we sold the cable to the German Government, and before they took over its working, we had two breaks which cost £13,000, just £1,400 less than the repairs of the whole previous 17 years. That is very hard upon us, but there is no help for it. We have distributed all the money we received, and thus ends finally the German Union Telegraph and Trust Company, which has been very useful to the German Government and the public. I am bound to say that the German Government have used us better than our own Government has treated the Submarine Telegraph Company, and if the cables are going to fall into the hands of Governments I hope they will be dealt with in about the same way as we have been, or a little better, I hope. There now only remains, with great regret on my part and on the part of the Directors, to move the final winding-up of the Company. This meeting is called in pursuance of the Winding-up Act. The first resolution I have to propose is as follows:—

"*That the liquidators' accounts, submitted to this meeting, showing the manner in which the winding-up of the Company has been conducted and its property disposed of, be received and adopted.*"

You have had the whole statement in your possession for a month, and the money has been paid, except to a few shareholders who are absent out of town.

Count O. VON REICHENBACH seconded the resolution, which was carried unanimously.

The CHAIRMAN: The next resolution is as follows:—

"*That the books, accounts, and documents of the Company and of the liquidators thereto be retained by the liquidators, with authority to them to destroy the same after the expiration of one year from the dissolution of the Company.*"

Count VON REICHENBACH seconded the motion, which was unanimously agreed to.

The CHAIRMAN: That is the whole business of this meeting, and the German Union Telegraph Company is practically dissolved and buried.

Mr. WELLS: We are not a very large body of shareholders, although one can quite understand that this is not a very pleasant occasion to assist at—the decease of a Company like this which has given us a certain amount of profit. I think, however, that we are indebted to the liquidators

for the very prompt manner in which they have distributed the assets of the Company, and I therefore beg to move that a vote of thanks be given to Sir James Anderson and Mr. Payton for their services.

Mr. J. D. PENDER seconded the motion, which was carried unanimously.

The CHAIRMAN: We are very much obliged to you, gentlemen. We are very sorry to see the disappearance of a healthy company, but we must make the best of the position.

The meeting then separated.

The South of England Telephone Company (Limited).

The following is the report of the Directors of this Company for the year ending 30th April last, to be presented to the shareholders at the sixth ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, London, E.C., on Thursday, the 27th inst., at one o'clock :—

The expenditure on capital account for the past year amounts to £19,917. 12s. 6d., bringing the total of that account to £64,301. 19s. 2d. The revenue account shows a sum of £16,722. 2s. 4d. for subscriptions and rentals, and a net credit balance of £5,283. 9s. 11d., making, with the sum of £1,115. 0s. 8d. brought forward from last year, an available balance of £6,398 10s. 7d.

After providing for the preference dividends (£2,771. 9s. 5d.) which have been paid, a balance of £3,627. 1s. 2d. remains, out of which the Directors recommend the payment of a dividend on the ordinary shares of 1 per cent. for the year, free of income tax, which will absorb the sum of £3,000, leaving a balance of £627. 1s. 2d. to be carried forward.

The claim of the United Telephone Company for surplus instrument royalty and rent of the Brighton Trunk line, which was disputed by this company, has been settled.

The report gives a list of the completed Trunk lines, and announces that the following Trunk lines are in process of construction :—Canterbury—Deal ; Brighton—Hurst ; Faversham—Sittingbourne ; Brighton—Newhaven.

At the 30th April of this year, 1,901 exchange lines and 480 private lines were completed ; and 71 exchange lines and 20 private lines were in course of construction.

The Directors have to record with deep regret the death of their esteemed colleague, Mr. T. F. Campbell. The vacant seat on the Board has been filled by the election of Mr. Charles Billett. Mr. Alexander MacGregor retires from the Board by rotation, and, being eligible, offers himself for re-election. The shareholders' auditor, Mr. J. Weise, retires, and is eligible for re-election.

The following comparative statement of exchange and private line business is given in the report :—

	Exchange.	Private.
April 30, 1886	687	248
April 30, 1887	1,130	348
April 30, 1888	1,521	386
April 30, 1889	1,972	500

NEW COMPANIES REGISTERED.

THE ELECTRICITY SUPPLY COMPANY FOR SPAIN (LIMITED).—Registered by Slaughter and May, 18, Austinfriars, E.C., with a capital of £100,000 in £5 shares, of which 100 are founders' shares and 19,900 ordinary shares. Object: To form centres in any towns and districts in the Kingdom of Spain, at which electric power may be generated or accumulated, and from which the same may be distributed by means of wires or other conductors of electricity for the purpose of lighting private houses or street lighting, or the lighting of public buildings, shops, factories or works, or for the purpose of giving motive power or heating in all such places. There shall not be less than three nor more than seven directors. Qualification, £250 stock. Remuneration, £500 per annum, together with one-tenth of the net profits after 7 per cent. dividend, divisible as they determine.

THE ELECTRICITY SUPPLY CORPORATION (LIMITED).—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100,000 in £10 shares (100 of which are founders' shares). Object: To apply for, obtain, undertake and carry out a Provisional Order for the supply of electric light and power within the parish of St. Martin's-in-the-Fields, in the county of Middlesex, and also generally any contracts, Acts, Provisional Orders, Licenses, decrees and concessions for, or in relation to, the supply of electricity in Great Britain or elsewhere ; to carry on the business of electrical engineers, electricians, engineers and contractors, manufacturers of electrical and other apparatus, &c. The first subscribers are :—

	Ordinary Shares.
J. Irving Courtenay, 1, Elm-court, Temple, E.C.	1
J. Barclay, 5, Clarendon-place, Hyde Park-gardens	1
Sir D. Cooper, M.P., 6, De Vere-gardens, S.W.	1
L. W. Novelli, Oxford and Cambridge Club, S.W.	1
J. Meston, 75, Union-street, Aberdeen	1
F. D. Finlay, 75, Gloucester-place, W.	1
F. King, 65, Chelverton-road, Putney	1

There shall not be less than five nor more than ten directors. Qualification, 50 shares. The first to be appointed by the subscribers to the Memorandum of Association. Remuneration to be determined in general meeting.

CITY NOTES, &c.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupons due 1st July next on their Five per Cent. Mortgage Debentures will be paid on and after that date by Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

MESSRS. M'CULLOCH, SONS AND KENNEDY (LIMITED).—We announced on the 7th inst. that Mr. Rankin Kennedy had joined the firm of Messrs. M'Culloch and Sons, of Vulcan Works, Kilmarnock. A circular is issued by the firm announcing the completion of the arrangements for converting the firm into a limited liability concern under the old management. A circular from Mr. Kennedy states that he has transferred his patents and inventions in electrical engineering, together with his business formerly carried on at Woodside Electric Works, Glasgow, to the new firm.

METAL RECOVERY COMPANY.—The prospectus of this company has been issued this week, showing that the company is formed with a capital of £90,000 in £1 shares, principally to acquire the patent for Great Britain granted to Mr. J. E. T. Woods for improvements in the recovery of refuse metals ; also the right to take out patents in all foreign countries, British colonies and dependencies, and for the purpose of working and dealing with the same ; and also a patent provisional protection which has been granted to Mr. J. E. T. Woods for improvements in the manufacture of iron wire for telegraph and other purposes. The prospectus states that certain experimental works in connection with the recovery process have been put up, and some tons of tins have been successfully treated. The secretary of the company (*pro tem.*) is Mr. H. Cooper Mason, and the offices are at 72, Bishopsgate-street Within, London, E.C.

THE MINING AND GENERAL ELECTRIC LAMP COMPANY (LIMITED).—We are requested to state that on and after June 17th, the works address of the above company will be 64, Milbank-street, Westminster, to which place goods or communications should be sent.

WEST AFRICAN TELEGRAPH COMPANY.—The Directors recommend a dividend of 5s. per share in respect of the year ended 31st December, being at the rate of 2½ per cent. per annum. A year ago the distribution was 3s. per share.

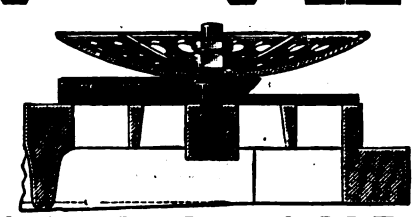
WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons due the 30th inst. on this Company's debentures will be paid by Messrs. Barclay, Bevan and Co. The coupons must be left three clear days for examination.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this Company for the half-month ended June 15, 1889, were £3,157, as compared with £2,971 in the corresponding period last year, showing an increase of £186.

ENDOLITHIC IVORY.—At the Royal Military Tournament now being held at the Agricultural Hall, Islington, the badges used by H.R.H. the Prince of Wales, H.R.H. the Duke of Cambridge, the officers and gentlemen composing the various committees, and the judges, staff, and competitors, have been made by the Endolithic Ivory Company.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 580.—Vol. XXIII. FRIDAY, JUNE 28, 1889. Price Fourpence.

NOTES.

It will be seen by the verbatim report of Lord Trayner's judgment, which we publish in another column, that the Brush patent, No. 2,003, of 1878, has been invalidated. The claims contested, it will be remembered, were those for a peculiar form of commutator and a compound-wound machine. The claim for a commutator with "detachably attached sub-segments" has been held to be invalid, by reason of the claim in the final specification being "larger and different from that claimed in the provisional specification." Lord Trayner also holds that Brush's compound-wound machine was anticipated by Varley both by publication and use. The wide importance of this judgment can hardly be over-estimated, although, of course, the decision cannot be considered final until it has stood the test of appeal.

Whatever may be the legal value of Lord Trayner's arguments, there can scarcely be two opinions as to their lucidity and unusual brevity. There occurs towards the end of the judgment a paragraph which will probably act in certain cases as yet another incentive to obscure specifications, if indeed such be required. "A specification," the learned judge remarks, "may so insufficiently describe the process or the machine patented as to render the patent invalid. It may, nevertheless, contain sufficient description to disclose or publish the invention so as to prevent its being validly patented by another subsequently."

We furnish our readers this week with an analysis of the Model Provisional Order which has been issued by the Board of Trade, in which the chief points of departure from previous practice are indicated. We have taken as our chief standard of comparison the Chelsea Order of 1886, which remains the only Order yet confirmed by Act of Parliament; but we have also compared and collated the Model Order with some of the most important draft Orders which formed the subject of the recent inquiry. It will be seen that as compared with the Chelsea Act alone (to say nothing about the draft Orders) the alterations are uniformly against the interests of the Supply Companies. At the same time we do not find any really serious cause of complaint save in two most important points, upon which we have written at length in another part of this impression.

We are frequently asked about the duties of Electrical Inspectors by people who do not chance to be familiar with the terms of Provisional Orders or Licenses, and for this, and other reasons, we have taken the opportunity in the analysis referred to above to reprint the whole section relating to "Testing," as well as much of that relating to meters.

The meeting of the Electrical Section of the Chamber of Commerce was well attended as far as the General Committee was concerned, but the number of members present was disappointingly few. A resolution was passed, confirming the recommendation of the Committee that members should be deemed to have the right to attend every Committee meeting, and to speak on the invitation of the Chairman. An interesting report was read on the work of the Section, and copies were ordered to be furnished to the technical journals. Some discussion took place on the Model Order, when it appeared that those members who had made themselves acquainted with its contents felt the strongest objection to certain clauses. There was some talk of the Chamber appearing before Parliament in its corporate capacity to oppose the decision of the Board of Trade, but it appeared that those who are interested in Orders which they hope to get confirmed this session thought that, however objectionable these clauses might be, it would be impolitic to oppose them, and thus to risk the safety of the Bills.

It is easy enough to understand the feeling of anxiety to avoid everything which may tend to jeopardise the passage of the Bills, but on the other hand, it is certainly very unfortunate that the industry should have to submit to a Model Order which is open to such serious criticism simply because motives of policy prevent some of the leading men from joining to oppose it. As regards the County Council, we suppose we must make up our minds to submit unless the protest of the Paddington Vestry finds support—as we trust it may—in all the London vestries. But as regards the Inspector Clauses, we are happy to believe that they are so bad that they cannot possibly long survive the ordeal of actual enforcement.

Sir Arthur Blackwood's rejoinder to the United Telephone Company does not seem to carry the dispute much forwarder, or to help the public to a better understanding of its bearings. The necessity for some fuller and clearer statement than has yet been vouchsafed on the part of the Post Office is evidenced by the articles which appeared in last week's *Economist* and *Saturday Review*, both these high-class journals, though in

Digitized by Google

opposite ways, misconceiving the issues, and misrepresenting the facts. The *Saturday Review* especially is singularly ill-informed on the whole subject; and when such leaders of public opinion as these go so far astray it is plain that a perfectly trustworthy account of the situation is very much needed. For one who "declines to be drawn into any further controversy," Mr. RAIKES, through the medium of the Secretary of the Post Office, is tolerably controversial on one point at least; but it happens not to be a very material point, the real question turning not upon whether amalgamation was intended or contemplated, but whether in the strict terms of their licenses the telephone companies can legally amalgamate.

As to the incidents upon which the United Company have, as we think, indiscreetly laid so much stress, the POSTMASTER-GENERAL seems to have decidedly the best of the argument. Even apart from historic facts it is pretty plain on the face of it that the Post Office never contemplated their amalgamation or the companies would not each have had a license covering the whole country. And, on the other hand, the parent company could hardly have been contemplating their amalgamation when it restricted its subsidiary companies to clearly-defined and separate areas—to say nothing of the large pecuniary interest it had in keeping them apart for the purpose of its own royalties. Mr. RAIKES still speaks of the amalgamation as only "projected," and it remains to be seen whether the companies will run the risk—real or apparent—of disregarding his warning. If they do, there is the contingent possibility of their business coming to an end next year; if they adopt the other course, dropping the project altogether, they will have a very substantial complaint against the Post Office, in which the public may sympathise, for hindering the natural development of telephonic industry.

IN common with many other electricians, we were much disappointed to find that the distinguished party of American Engineers, which has just left our shores, included so very few members of the electrical profession. We learn from our New York correspondent that it was at one time proposed by the American Institution of Electrical Engineers to organise with the other Societies for the purpose of a combined trip, but the idea fell through, owing chiefly to the fact that such a large proportion of the electrical engineers who were crossing the Atlantic were going on business which did not admit of any arrangement of this character. Amongst those who have already started are Messrs. T. D. LOCKWOOD, C. PRICE (of the New York *Electrical Review*), CARL HERING, LEWIS SEARING, J. M. SMITH, and PHELPS. Our correspondent adds that it is not unlikely that there will be a good muster at Newcastle for the British Association meeting.

ON the 28th March last, at the Institution of Electrical Engineers, Prof. AYRTON read at short notice a most valuable Paper by Prof. PERRY and himself under the title of "Laboratory Notes on Alternating-Current Circuits." Owing to the fact that the subject was not announced through the usual channels, and that the attendance was consequently somewhat meagre, this Paper has not hitherto received the attention which it deserves, and although it has since been published in the *Journal* of the Institution we have thought proper to reprint it in our columns. Next week, when the Paper will be completed, we hope to have something further to say upon the subject.

THE memorandum of precautions to be observed in the use of the electrostatic voltmeter, which has been drawn up by SIR WILLIAM THOMSON, and which will be found in another column, ought certainly to prevent a repetition of the recent sad accident at Messrs. SIEMENS' works. If the outer wooden case advocated in paragraph 3 had been employed, the inquisitiveness of the unfortunate man CONNELLY would not have been attended with fatal consequences.

WE print on another page the Bye-laws proposed by the Borough of Bradford in connection with the Corporation Supply of Electricity. Objections must be sent to the Board of Trade before 6th July. There is nothing calling for special remark in these regulations themselves, but they are of some interest as being the first example of the kind which has yet occurred.

Dundee.—We learn that the order for the lighting of the Albert Institute in this town has been placed with Messrs. Paterson and Cooper.

The Electric Sugar Swindle.—Howard, one of the Electric Sugar swindlers, has been sentenced to nine years and eight months' penal servitude.

Northampton.—At a special meeting held last week the Northampton Town Council gave their consent to the application for an electric lighting license by the Northampton Electric Light and Power Company.

Coventry.—The National Telephone Company opened an Exchange at Coventry on Monday last, and the town is now in telephonic communication with Birmingham, Sheffield, Nottingham, and the Black Country.

An Opening.—Ex-Consul Smith, of Carthagena, says that the Republic of Colombia presents a vast field for enterprise. Electric lights, waterworks, railways, and ice machines are particularly wanted just now, and the Government is "liberally disposed."

Nottingham.—The plans for the central station of the Nottingham Electric Light and Power Company will be submitted to the Corporation by the end of the month. The contract for the entire work has been undertaken by the Electric Construction Corporation.

The Halifax and Bermudas Cable Company.—In answer to a question by Dr. Cameron on Tuesday last, Mr. Jackson said the £15,000 deposit of this company had been received on the 7th of June, and had been invested in the name of the Paymaster-General.

Sale of Manufacturing Plant.—It will be seen by our advertisement columns that an important sale by auction of manufacturing plant and engineers' sundries will take place next week at Birmingham. Catalogues can be obtained of Messrs. Wheatley, Kirk, Price and Goulty.

Henley's Telegraph Works Company.—This company is about to ship 68 knots of submarine cable for the West Indies. They are also engaged in making a length of submarine cable for Denmark, and we hear that they will commence work almost immediately on the cable to connect Halifax (Nova Scotia) with Bermuda.

Digitized by Google

Glasgow.—At a special meeting of the Glasgow Town Council on Monday last, it was decided to give notice of the intention of the Corporation to apply for a Provisional Order to supply electricity for public and private purposes. Messrs. Muir, Mavor and Coulson have also announced their intention to apply for a Provisional Order.

Edinburgh.—A Company called the Scottish Electric Supply Company has been established to undertake the work of electric lighting and the supply of electric power in Edinburgh and surrounding districts. A suitable site for the central station has been secured at Lochrin, adjoining the Union Canal, Edinburgh, where there is room for extension with every facility for the supply of coal.

The Electric Meter Competition in Paris.—The first meeting of the committee nominated by the town of Paris to judge the competing electric meters took place on June 12th. The competitors are 27 in number, although only 18 have sent actual apparatus; the rest have contented themselves with sending in drawings and photographs. It is said that a large proportion of the instruments possess considerable novelty.

The Franco-Chinese Telegraphic Contract.—According to Indian *Engineering* information has been received of the definite conclusion of the telegraphic contract between France and China on the Tonquin frontier. By this arrangement a wire will be laid down between Langson and Langchow, the capital of Kwangsi—80 kilometres from each other—and direct telegraphic communication will be then established between Saigon and Pekin.

Higgins' Single-Wire Column Printing Telegraph.—We have received from Mr. F. Higgins a sample of his new single-wire type-writer's performance. The printing is exceptionally clear, and being in column form instead of in slip is far more convenient to read. We learn that the Exchange Telegraph Company, who are the sole proprietors of the patents for these instruments, intend to take legal proceedings against all persons infringing their patents.

Bristol.—Mr. Preece has sent in a report of a very lengthy character to the Electrical Committee of the Bristol Town Council. It refers to what has been done in other towns in the matter of electric lighting and the results that have been obtained. Electricity cannot, he says, be supplied as cheaply as gas. As a motive power, he points out that electricity could be obtained cheaper in Bristol than in London and other places, on account of the difference in price of coal. Finally, Mr. Preece considers it advantageous for corporations to undertake their own lighting.

St. James's Vestry.—The St. James's Vestry passed the following resolution:—"That Messrs. Trinders and Co. be informed, in reply to their notice of the intention of the St. James's and Pall Mall Electric Light Company to apply for a Provisional Order, under the Electric Lighting Acts, in the next Session of Parliament, that the Vestry are not prepared to assent to the said company applying for a Provisional Order until they have acquired a generating station in the northern part of the parish, or are otherwise in a position to supply electricity throughout the whole parish."

Electric Traction on the North Metropolitan Tramway.—The first of the Electric Traction Company's cars, having been duly licensed by the police authorities and the Board of Trade, commenced running on the Barking-road section of the North Metropolitan Tramways Company on the 14th inst. A second car was put on the following day, and the six cars which will shortly entirely supersede horses will be placed in active work as soon as the drivers become accustomed to the new form of traction. These cars carry 52 passengers, and do 17 journeys daily with one change of accumulators.

Paddington Vestry.—The Vestry of Paddington, at a meeting last week, after considering the letter of the London County Council, addressed to the Board of Trade, on the subject of electric lighting, carried a resolution expressing the strongest exception to the proposals therein made for transferring the control and purchase of electric lighting in the metropolis from the Corporation, the vestries, and the district boards, to the County Council. The Vestry further resolved to forward a statement of its objections to the Board of Trade, the County Council, and the other representative governing bodies of the metropolis.

S.s. "Silvertown."—The India Rubber Gutta Percha and Telegraph Works Company has received a telegram from Mr. Matthew Hamilton Gray, engineer in charge, saying that the cable steamer "Silvertown" had successfully removed three faults from the cables connecting Dakar (Senegal) with Teneriffe without interrupting the working of the lines. As one of these faults was in the neighbourhood of Teneriffe and the other two near Senegal, some 800 nautical miles southward, and the work was carried out in about ten days, those engaged in the operations are to be congratulated on their success. The "Silvertown" is expected to arrive in London on 5th prox.

Personal.—A presentation took place at the offices of the Telephone Company of Ireland last week to Mr. Robert Morris, on his leaving the country for America. Mr. Morris has been with the Company from its inauguration to the present time, and is one of the best-known exponents of this branch of electrical science in Ireland. He was a general favourite with the public and the members of the staff, and his departure has caused universal regret. A very handsome non-magnetic silver watch and chain was subscribed for, and it was presented to him in the presence of the staff, who joined heartily in the general expression of goodwill and wishes for his future success.

The Proposed Electrical Engineering and Inventions Exhibition.—The first public meeting in connection with the Electrical Engineering and Inventions Exhibition, which it is proposed should be held in Edinburgh next year, took place on Thursday last week, Sir Thomas Clark, Bart., presiding. The Chairman moved—"That it be remitted to an interim executive committee, with power to add to their number, to carry out the Exhibition scheme, and to report progress to a future meeting of the general committee, to be held at such time as the interim executive committee consider advisable." After some little discussion, in which the necessity for a good site was strongly insisted upon, the motion was agreed to and the proceedings terminated.

Another Exhibition.—An Exhibition, to be called the Brighton and Hove International Exhibition of Arts, Sciences, Manufactures and Trades, is to be held at Hove in October next under the patronage of the leading local authorities of the neighbourhood. The exhibition building will be ready for exhibits on September 30th, and will remain open till Christmas. There will be a section devoted to electricity, and negotiations are in progress with the railway companies to obtain a special carriage rate for goods sent to the exhibition. Applications for space should be sent to the general manager at the offices, 14, Pavilion-buildings, Brighton, or 20, Bucklersbury, London. We wish Mr. Philip Shrapnel, the general manager, who is well known in connection with the various Exhibitions held in London, every success.

The Schoop Accumulator.—The chief object aimed at in the Schoop accumulator, which is manufactured at the well-known Oerlikon Works, is to attain durability, even when the cell is subjected to excessive charges and discharges. The grids, which are of triangular section, contain two-thirds the amount of litharge usually employed. It is said that with these plates there is no trouble from buckling or from the plugs falling out. The smallest-sized cells contain 11 plates, 2·5 millimetres thick and 14 centimetres square. The total weight of a complete cell is 7 kilogrammes, the plates weighing 4·5 kilogrammes. When discharged at the rate of 10 amperes and 35 amperes, their capacity is respectively 50 ampere-hours and 32 ampere-hours. The cells may be then discharged at any rate up to 70 amperes without sensibly diminishing the capacity.

Sherlock and Pattison's Engine-room Telegraph, and Mills Boat-Lowering Gear.—On Wednesday last a party of gentlemen, including Admiral Greville, Sir James Anderson, and others interested in the subject, left the Temple Pier for the docks in one of Messrs. Immisch's electric launches to inspect some boat-lowering gear and a new engine-room telegraph, fitted on board the Eastern Telegraph Company's cable ships, "Mirror" and "Electra." Mr. Mills' boat-lowering tackle showed itself very simple and effective. On board the "Electra" there was a

Digitized by Google

very practical addition to the ordinary engine telegraph. On turning the handle to any order on the bridge dial, a simple attachment from the engine-room dial to the reversing gear causes a bell to ring both on the bridge and in the engine-room until the order has been properly obeyed. It is the joint invention of Mr. Sherlock, the head engineer, and Captain Pattison of the "Electra," and should be found very useful.

Brighton County Court.—At the Brighton County Court last week, the attention of the Judge was occupied for some time in hearing an action brought by James Foley Field, of Montague-street, Worthing, to recover £10 from the Brighton Electric Light Company as charges for allowing a pole and wires to remain on the premises No. 22, North-road, Brighton, where they had been erected as alleged without his permission. Defendant paid £1. 10s. into Court, without admitting liability. The evidence showed that a pole was fixed by arrangement with the landlord, and that it was simply replaced during the plaintiff's tenancy. His Honour held that a slight trespass had been committed by the defendant's men in going on the roof to change the old pole for a new one without permission of the plaintiff, but considered that sufficient had been paid into Court. A verdict was therefore given for the defendants.

A New Wire Process.—We learn that wire is now being manufactured—whether iron, copper, or brass—by a new and greatly-improved process, and at a considerably reduced cost. The machine devised for this purpose consists of a series of rolls in a continuous train, geared with a common driver, each pair of rolls having a greater speed than the pair preceding it, with an intervening friction clutch adapted to graduate the speed of the rolls to the speed of the wire in process of rolling. The entire operation of producing the smallest-sized wires from rods of one-half inch is done cold. It is alleged that this method obviates the danger of unequal annealing and of burning in the furnaces—in addition to this, the wire being more flexible and homogeneous than that made by any ordinary method, and capable of sustaining greater longitudinal strain; in the case of copper wire there is said to be a greatly increased electrical conductivity.

The Birmingham Electrical Exhibition.—The Executive Committee of the Electrical Exhibition in Bingley Hall are making arrangements for the introduction of several features of an interesting character. One novelty which has been decided upon is that of showing the practical workings of a coal mine. The mine will be lighted with electric lamps, and every visitor to the workings will be expected to carry a lamp so as to find his way about. Another feature will be the introduction of a telpher line, the order for which has been placed in the hands of the United Electrical Engineering Company, of Westminster. Mr. Vertegans has undertaken to construct an electrically-illuminated cascade and rockery, and an imposing electrical fountain will be arranged in the centre of the hall. The fountain will be an exact reproduction of the one in the court-yard of the Grand Hotel at Paris. This will be carried out under the superintendence of Messrs. Fowler and Lancaster, the electricians of the Exhibition.

Rare Metals.—The following list of the prices of rare metals, which we take from an American source, may be of service to some of our readers:—

	Per oz.		
Gallium	£650	0	0
Vanadium	64	0	0
Thorium	54	0	0
Glucinum	50	0	0
Zirconium	50	0	0
Lanthium	35	0	0
Cerium	32	0	0
Didymium	32	0	0
Lithium	32	0	0
Calcium	30	0	0
Yttrium	29	0	0
Erbium	28	0	0
Niobium	26	0	0
Strontium	26	0	0
Barium	16	0	0

	Per oz.		
Iridium	£11	0	0
Asmium	10	10	0
Rhodium	8	10	0
Palladium	6	10	0
Gold	4	0	0
Chromium	3	5	0
Indium	2	10	0
Platinum	2	0	0
Telurium	1	15	0
Potassium	0	10	0
Silver	0	4	0
Aluminium	0	3	0
Cobalt	0	2	0
Nickel	0	0	2½

Electric Welding of Pipes.—The *Engineering and Mining Journal* (New York) says:—"What was certain to follow the invention and development of electric welding of solid bodies by Prof. Elihu Thomson was that either he or some other worker in the same field of research would discover a method of making endless pipes by the adaptation of the discovery to that purpose. This has apparently been done by Mr. Elias E. Ries, of Baltimore, and patents have been granted covering the process. The main feature of the first patent is that the smooth interior of the pipe is secured by the use of a removable refractory core, made of some insulating material, while in the second case the same object is attained by subjecting the interior of the pipe while being welded to compressed air or fluid pressure. We expect to see this system largely adopted, especially in pipe lines and where the pipes are to be subjected to high pressure, as welded joints must, of their nature and from the tests made of welded bars, be stronger than any ordinary joint and proof against all leakage."

The Eiffel Tower Projectors.—In a recent issue of *La Nature* there appears a very striking illustration of the Eiffel Tower lit up on the opening night of the Exhibition, taken from what must have been a most successful photograph. It shows very clearly the diverse effects of the coloured fires, the lines of gas lamps, and the electric projectors on the summit of the tower. The latter resemble the arrangements of a first-class lighthouse, but the light is much more powerful. The arcs have a rated power of 5,500 carcels, which is concentrated by lenses and multiplied by reflection to six to eight million carcels in the direct ray, being the most intense luminous projection yet attempted. It is visible at the ground level to a distance of 67 kilometres; but by a spectator at an elevation sufficient to neutralise the curvature of the earth it should be seen at a distance of 203 kilometres. It has actually been detected from Bar-sur-Aube, which is 190 kilometres from Paris, by an observer placed on a hill 300 metres high. At these distances it appears as a simple luminous point.

A Movable Electric Light Station.—The Cumberland Valley Railroad Company, says *Invention*, has just completed at its shops at Chambersburg, Pa., a movable electric light station of wonderful illuminating power, and a novelty in railroading. It is intended to furnish light for wrecking purposes. The main car is 33ft. long by 9ft. wide, and 13½ft. high. The floor is of iron. In one end is a 40 horse-power vertical boiler and a 35 horse-power vertical automatic engine. The engine and boiler rest upon a cast-iron floor plate 9ft. by 11ft. In the other end of the car are two dynamos, one of 25 lights, the other of 15 lights, both of 2,000 candle-power. The dynamos are connected by belting with the engine. Under the car the lamps are carried, and also the tools for erecting the line. Attached to the car is a tender, to supply water and coal for the engine. Upon the tender are racks for carrying the poles, hoods for lamps, and a reel for holding the wire. The poles are made of hollow iron piping, of a handy and convenient pattern. The car will form a novel auxiliary to the equipment of the road, and it has attracted much attention from railroad men.

The late M. Gaston Planté.—A correspondent writes as follows:—"The news of the death of M. Gaston Planté has been received throughout the country with feelings of the deepest regret. It is strange that, although his genius and ability were universally recognised, so little is known of his very able book, entitled "The Storage of Electrical Energy," which contains a description of all his experiments with voltaic batteries, which finally led to the well-known form of Planté cell. Besides his experiments with all the common metals as voltaic couples, there are extremely interesting articles on the discharge of high-tension currents and globular lightning. It is doubtful if this latter subject has ever before been treated so completely, or with so many well-authenticated instances, which stand beyond dispute. The book cannot be too strongly recommended to all who have to do with secondary batteries, as it contains notes by the original inventor on the practical management of accumulators, and explains all the small but important difficulties which are so often met with, but which may be easily remedied and avoided by a little knowledge of their theory."

Barmen.—The following are some additional details respecting the central station at Barmen, an account of which appeared in *The Electrician* of May 17th. The plant comprises

Digitized by Google

two Galloway boilers, working at 120lb. pressure, and two compound 100 horse-power engines running at 110 revolutions. Each engine drives two shunt machines, running at 500 revolutions, and having an output of 31 kilowatts, the present output of the station amounts to 104 kilowatts, the dynamos working 10 hours per diem and the storage-batteries doing the work the rest of the day. The distribution, as we mentioned in our previous account, is carried out on the three-wire system. Two sets of Tudor accumulators, arranged 68 in series and two in parallel, are connected across the mains, and by means of a switch which cuts out cells as required it is possible to keep the load on the dynamos always equal by sending the excess of current through the accumulators. The maximum rate of discharge of the cells is 220 amperes, and as the demand on the station at one time never exceeds 90 kilowatts, lasting six hours (3 p.m. to 9 p.m.), the accumulators can, if necessary, manage the load for eighteen hours out of the twenty-four. The Aron meter is used throughout, and the charge is 9d. per 1,000 watt-hours.

Barnet.—At the meeting of the Barnet Local Board, last week, the Lighting Committee submitted their report, recommending that the account of the electric lighting contractor, amounting to £95. 17s., for 71 lamps for three months, be paid. This recommendation, it was stated, had been arrived at after a long discussion. After some remarks, it was decided to pay the account. The Clerk read the draft of a letter in reply to one from Messrs. Ingledew, Ince and Co., dated the 14th ult., in which, it may be recollected by our readers, they complained of the resolution passed by the Board, declining to assist Mr. Joel in obtaining a Provisional Order, which would enable him to put the wires underground as required by the contract. The principal points in the draft were that Mr. Joel would not at present be called upon to lay the wires underground—the Board being disinclined to give him permission to break up the streets for this purpose; and they therefore released him from the obligation. At some future time, when affairs were more satisfactory, the Board might be induced to consider an application for a license extending over the term of the contract. It was agreed that the letter should be written, the Chairman remarking that he thought it expressed the feelings of the Board.

Fatal Accident at Siemens' Telegraph Works.—An inquest was held on Thursday last on the body of John Connelly, aged 31, a pensioner from the Royal Engineers, who was killed whilst at work at Siemens' Telegraph Works, Charlton, by an electric shock. Henry Percy Haynes, clerk in the electric-light department, said that at the dinner-hour on Tuesday he was in his office, when his attention was called to a man lying on the floor of the electric-light shop. He ran out and found Connelly lying on the floor with Sir William Thomson's electrostatic voltmeter in his hand. Alfred Dykes, electrical engineer, in the employ of Siemens Brothers, said that when he left at one o'clock he told deceased to keep the engine running steadily, and that if anything went wrong to stop the engine, and not attempt to touch any of the machines. Deceased had no business at or near the voltmeter; in fact, witness had several times warned him not to touch it. The pressure at the time was 1,000 volts. Edward Lankert, chief of the electric-light department, said that if one of the terminals of the instrument had been covered with a non-conducting material the accident would not have occurred. Dr. Hughes said that he was sent for and found deceased dead in the light shop. There were violet-coloured streaks up the right hand, with a perforation in the palm. In the left hand were three perforations. The heart and all the organs were healthy. The deceased had met his death from a shock of electricity.—The jury returned a verdict of "Accidental Death," and attributed no blame to the firm.

French v. English Electrical Engineers from a Yankee Point of View.—The Paris correspondent of the *New York Times* says:—"The jealousy of the French electricians, who are far behind the English in practical ability and knowledge, yet have fought bitterly against allowing any foreigners to share in the lighting contracts, has prevented anything like an intelligent use of the tower as yet for spectacular effects in illumination; but these will come in time, and no doubt they will be notable when they do come. The same spirit kept the question of elevators for the tower open until every other expedient had been tried, and recourse to an American firm was absolutely necessary. A whimsical story was told me the other day about the effort to shut the English firm out of the competition for working the coloured fountain display. Week after week the contracts which had been verbally promised the English company were delayed, after they had been fairly won, and at last it was announced that there would be another competition, conducted on slightly different lines, which necessitated rearranging the whole plant. While the English company were engaged in this, the manager noticed a suspicious number of young men with very commonplace clothes, but curiously white hands, loitering and sauntering about, but keeping a sharp watch in a furtive way on the English workmen. With great shrewdness he had the whispered word passed around to do everything wrong, regardless of expense or results, as long as the spies were about, and the men, entering into the spirit of the thing, elaborately mystified them. At night, when the new competition came on, the English had set everything right and gave a better display than ever, while the Frenchmen broke down with grotesque completeness at the outset. Thus it was that the English finally got their contract."

Leeds.—The Electric Lighting Committee of the Corporation of Leeds issued last Friday to the members of the Town Council a report, consisting of 27 pages, in which are reviewed the proceedings of the committee since its formation, and the particulars of a scheme for lighting the town from a central station. It appears that the committee have expended £10,233. 18s. 11d. on capital account, which is the sum the Council granted for experiments. The report goes on to say that whilst the Council's instruction to the committee were limited to making experiments in and about the Town Hall, in compliance with a generally-expressed wish it has deemed it its duty to go into the question of lighting with electricity the centre of the town. To secure the best possible method the committee has visited various towns where the electric light is used, and then sought information from the tenants of shops bounded by Albion-street, Boar-lane, Briggate, and Commercial-street, to ascertain the disposition of the tradespeople in regard to an electric light supply. The desire to have the electric light was almost unanimous. The committee then mapped out the district bounded by Vicar-lane, New Market-street, Duncan-street, Briggate down to the Bridge, Boar-lane to the New Station, Park-row, Guildford-street, Upperhead-row, New Briggate, and North-street to Vicar-lane, and, after ascertaining the exact number of lamps which would be required in a given area, and using this as a basis, it was found that the number of public and private lamps required for lighting this district would be about 37,500. The piece of land known as "the Midden" has been fixed upon for the central station, and tenders show that the machinery and other plant required will cost in all about £58,000. To supply private residences, however, would cost an additional £10,000, making in all £68,000. As to the question of cost, the committee is of opinion that an incandescent 10 candle-power lamp can, after paying for depreciation and interest, but not making a profit, be run for one-eighth of a penny per lamp per hour. Comparing this with the present price of gas in Leeds, electric lighting can be supplied at 20 per cent. above that price; but as the customers would have in addition to pay for renewing their lamps this would probably add 40 per cent. to the total cost, according to the present price, or taking gas and meters at 2s. per 1,000 feet, the electric light would in price be equal to gas at 3s. 5d. per 1,000 feet. The report then recommends that portions of the Town Hall and Municipal Buildings be lighted by electricity at a cost of £3,000; that the Council apply to the Board of Trade for a Provisional Order authorising the Corporation to provide and supply electricity for public and private lighting purposes within the area referred to in the report, at an estimated total capital expenditure of £68,000; that the Council authorise the Electric Lighting Committee to carry out and complete an initial installation of electric lighting within the district mentioned in the report, at an estimated capital expenditure of £25,000, such sum being part of the sum of £68,000 to be borrowed under the authority of the Provisional Order.

PRECAUTIONS FOR SAFETY IN THE USE OF SIR W. THOMSON'S ELECTROSTATIC VOLTMETERS.

BY SIR W. THOMSON.

[We have been furnished with a copy of the following memorandum of precautions to be observed in using Sir William Thomson's electrostatic voltmeters in connection with alternating or continuous current dynamos, and which will be issued with all instruments supplied.]

§ 1. In all applications in which one of the two conductors connected with the voltmeter is kept permanently connected with the earth, this conductor should be connected with the outer case of the voltmeter. The other conductor is to be connected with the insulated terminal, and must be carefully guarded against accidental contacts.

§ 2. To provide for use in any application not fulfilling the condition of § 1, all the electrostatic voltmeters are supplied with thoroughly insulating feet; and the precautions stated below in § 3 and § 4 must be observed.

§ 3. The vertical-scale voltmeter for from 400 to 12,000 volts, when set up for permanent use, should be enclosed in a case (which may be of wood with a glass front) preventing any person from accidentally touching the metal case or the terminals of the instrument. The vibration-checker is worked with perfect safety by a silk cord passing through a hole in the wood or glass of the protecting case to the front outside. For temporary or experimental applications the user must take his own precautions; an outer enclosing glass case might be found too cumbrous.

§ 4. For ordinary domestic electric lighting or other applications to less than 200 volts, the multicellular voltmeter may be left unprotected so far as personal danger is concerned; but, to avoid chances of damage to instruments or wires, or of melting a fuse, its outer case, as well as its terminal insulated from the outer case, ought to be perfectly guarded against accidental contacts when the instrument is set up for permanent use. Glass and vulcanite sheaths are provided for this purpose by the instrument-maker when desired.

§ 5. *General Warning.*—Never open the case of the vertical-scale voltmeter to change its weights, nor touch its terminals to connect or disconnect (or to secure either connection if imperfectly made), without being sure either that the dynamo is not running or that both the conductors leading to the voltmeter are safely disconnected from its circuit.

§ 6. It may be asked, with reference to the vertical-scale voltmeter, why is the inner case made of metal? The answer is, that the electric conditions for definiteness of measurement require the vane to be protected all round from sensibly disturbing influence of any substance, other than the air around it, differing in potential from itself unless at the same potential as the quadrants. Why, then, not coat the metal inner-case with wood or vulcanite, or other non-conducting material? Answer: The protection thus imagined might be delusive when 10,000 volts is dealt with. Safety is most surely secured by an outer case an inch or so from the inner metal, unless, *which is always best when it can be arranged for*, one of the conductors is kept connected with the earth, and with the metal case of the electrometer also connected with the earth.

THE MODEL ORDER (METROPOLITAN AREA).

The chief points of difference between the clauses of the Model Provisional Order (Metropolitan District) which has just been issued, and the stipulations most commonly found in earlier Orders, are summarised below. We also print at full length the entire section relating to "Testing" and part of that relating to "Meters," much of which will be of interest at the present time to a wide circle of readers.

The term "energy," which is defined to mean electrical energy, is used throughout instead of "electricity" or "electric current."

A clause is inserted forbidding the Undertakers to acquire the business of any other Supply Company without the consent of the Board of Trade under penalty of revocation of Order.

Nature and Mode of Supply.

The following additional clause appears under this head:—

Systems and mode of supply. 9. . . . . (2.) The Undertakers shall not permit any part of any circuit to be connected with earth except so far as may be necessary for carrying out the provisions of any such regulations or conditions as aforesaid, unless such connection is for the time being approved of by the Board of Trade with the concurrence of the Postmaster-General, and is made in accordance with the conditions, if any, of such approval; and

(3.) The Undertakers shall so construct their mains and other works of all descriptions, and shall so work their undertaking in all respects, as not injuriously to affect by induction or otherwise other electric circuits from time to time used or intended to be used for the purpose of telegraphic, telephonic, or electric signalling communication, or the currents in such circuits; but as regards electric circuits erected or laid down for the purposes aforesaid after the construction of such mains or works, the provisions of this subsection shall only apply if reasonable and proper precautions have been taken in the erection or laying down of such last-mentioned electric circuits, and if they have not been erected or laid down in unreasonably close proximity to such mains or works. If any question arises as to whether the undertakers have constructed their mains or other works, or work their Undertaking, in contravention of this subsection, such question shall be determined by arbitration.

Works.

The following additional clause appears under this head:—

Prohibition of Overhead Wires. 11. . . . . The Undertakers shall not, without the express consent of the County Council, place any electric line above ground, along, over, or across any street.

If the Undertakers place any electric lines in contravention of this section they shall be liable to a penalty not exceeding ten pounds for every such offence, and in the case of a continuing offence to a further penalty not exceeding five pounds for every day after the first day during which such offence continues.

Where any electric lines of the Undertakers have been placed above-ground as aforesaid before the commencement of this Order they shall be removed by the Undertakers within a period of two years after such commencement, and if not so removed may be removed by the local authority or by the County Council (if the street is repairable by them), and sold by public auction or private contract for such sums and to such persons as the local authority or County Council may think fit; and the local authority or County Council may out of the proceeds of such sale reimburse themselves the amount of the costs of the removal and sale, and the balance of the proceeds of sale (if any) shall be paid over by them to the Undertakers. . . .

The whole of the clauses relating to the serving of notices and maps upon the local authority and the Postmaster-General, the breaking up of streets, alterations to pipes, wires, &c., under streets, and interferences with the service of the Telephone Companies, remain practically unaltered. The following new clause is added at the end of the section:—

Provision as to subways. [31 and 32 Vict. c. lxxx.] 18. If any subway has been constructed within the area of supply, whether before or after the commencement of this Order, to which the Metropolitan Subways Act, 1868, applies, that Act shall apply to any electric line of the Undertakers as if electric line had been included in the term "pipe" as defined by that Act, and as if this Order were a special Act of Parliament.

Compulsory Works.

Clauses 19 and 20 have been remodelled as follows:—

Mains, &c., to be laid down in streets specified in Second Schedule. 19. The Undertakers shall, within a period of two years after the commencement of this Order, lay down suitable and sufficient distributing mains for the purposes of general supply throughout every street or part of a street specified in that behalf in the Second Schedule, and shall thereafter maintain the same.

Mains to be laid down in remainder of area of supply. 20. In addition to the mains specified in the last preceding section the Undertakers shall, *at any time after* the expiration of eighteen months after the commencement of this Order, lay down suitable and sufficient distributing mains for the purposes of general supply throughout every other street or part of a street within the area of supply, upon being required to do so in manner by this Order provided.

[It would appear from this that the Undertakers are not at liberty to supply energy beyond the scheduled district of the area until after the lapse of 18 months. Six months is allowed for the carrying out of the work after notice of requisition.]

Digitized by Google

The clauses relating to requisitions to supply current have been remodelled, but the only practical difference is to allow the Undertakers, *if they please*, to accept a guaranteed rental amounting to *less* than 20 per cent. of the cost of the extension.

TESTING.

We now come to the Section on Testing, which we reprint in full. In the first paragraph (Clause 28), the words "County Council" replace "Local Authority." Other changes which are not numerous are indicated in square brackets.

Appointment of electric inspectors by County Council. 28. The County Council, so long as they are not themselves the Undertakers for the purposes of this Order, shall from time to time appoint, and keep appointed, one or more competent and impartial persons to be electric inspectors for the purpose of inspecting electric lines and works and of certifying meters under this Order.

Appointment of electric inspectors by Board of Trade in certain cases. 29. If no electric inspector is appointed by the County Council [in earlier Orders and in the Chelsea Act the following words are interpolated here:—"*or if the inspection of mains or works is imperfectly attended to by the local authority*"] or if the County Council themselves become the Undertakers for the purposes of this Order, the Board of Trade, on the application of any person supplied with energy by the Undertakers within the area of supply, or of the Undertakers, may from time to time appoint, and keep appointed, one or more competent and impartial person or persons to be electric inspectors for the purposes aforesaid.

Remuneration of Electric Inspectors. 30. The County Council shall pay to every electric inspector appointed under this Order such reasonable remuneration (if any) as they, or (in case of an electric inspector appointed by the Board of Trade) the Board of Trade may from time to time determine, and such remuneration may be in addition to, or in substitution for, any fees which are directed to be paid to electric inspectors for services rendered by them under this Order, as may be settled by the authority by whom such remuneration is determined. Provided that where any such remuneration is settled to be in substitution for such fees as aforesaid, such fees shall, in lieu of being paid to such electric inspector for his own use, be due and paid to him on behalf and for the use of the County Council, and shall be carried by them to the county fund.

Testing of Mains. 31. Every electric inspector, if and when required to do so by the authority by whom he is appointed, shall from time to time test for insulation and conductivity any portion of any main of the Undertakers within the area of supply through which energy is, or is intended to be, supplied by them; provided that such testings shall not be made in regard to any particular portion of a main oftener than once in any three months, unless in pursuance of a special order in that behalf made by the Board of Trade.

Testing of Service Lines. 32. Every electric inspector, if and when required to do so by any person supplied with energy by the Undertakers, shall from time to time test for insulation and conductivity any service lines by which such energy is supplied and the efficiency of any joints in such service lines, and make such other tests in relation to such service lines as may from time to time be approved of by the Board of Trade.

Mode of testing. 33. Notice shall be given to the Undertakers before the commencement of any testing by an electric inspector, and such testing shall be carried out at such suitable hours as, in the opinion of such inspector, will least interfere with the supply of energy by the Undertakers and in such manner as such inspector may think expedient, but except under the provisions of a special order in that behalf made by the Board of Trade, he shall not be entitled to have access to or interfere with the mains of the Undertakers at any points other than those at which the Undertakers have reserved for themselves access to the said mains: Provided that the Undertakers shall not be held responsible for any interruption in the supply of energy which may be occasioned by or required by such inspector for the purpose of any such testing as aforesaid.

Report of results of testing. 34. Every electric inspector shall, on the day immediately following that on which any testing has been completed by him under this Order, make and deliver a report of the results of his testing to the authority or person by whom he was required to make such testing, and to the Undertakers, and such report shall be receivable in evidence.

[*New par.*]—If the Undertakers or any authority, company, or person are or is dissatisfied with any report of any electric inspector they may appeal to the Board of Trade against such report, and thereupon the Board of Trade shall inquire into and decide upon the matter of any such appeal, and their decision shall be final and binding on all parties.

Undertakers to establish testing stations. 35. The Undertakers shall at such places, within a reasonable distance from any distributing main, establish at their own cost such reasonable number of testing stations as the County Council [previously the Board of Trade] shall deem sufficient for testing the supply of energy by the Undertakers through such main, and shall place thereat proper and suitable instruments of a pattern to be approved by the Board of Trade, and shall connect such stations by means of proper and sufficient electric lines with such mains, and supply energy thereto for the purpose of such testing.

If any dispute arises between the County Council and the Undertakers as to whether the number of such testing stations and the distance from the main at which they are established is reasonable or excessive, or as to any excessive or improper use of energy for such testing, or as to the performance by the Undertakers of their duties under this section, such dispute shall be determined by arbitration.

Undertakers to keep instruments on their premises. 36. The Undertakers shall set up and keep upon all premises from which they supply energy by any distributing mains such suitable and proper instruments of such pattern and construction as may be from time to time approved of or prescribed by the Board of Trade, and shall from time to time take and record, and keep recorded, such observations as the Board of Trade may from time to time prescribe, and any observations so recorded shall be receivable in evidence.

Readings of instruments to be taken. 37. The Undertakers shall keep in efficient working order all instruments which they are required by or under this Order to place, set up, or keep at any testing station or on their own premises, and any electric inspector appointed under this Order may from time to time examine and record the readings of such instruments at such times and in such manner as he may be directed by the authority by whom he is appointed, and any reading s so recorded shall be receivable in evidence.

Electric inspector may test undertakers' instruments. 38. Any electric inspector appointed under this Order shall have the right to have access at all reasonable hours to the testing places and premises of the Undertakers for the purpose of testing the electric lines and instruments of the Undertakers, and ascertaining if the same are in order, and in case the same are not in order he may require the Undertakers forthwith to have the same put in order.

Representation of Undertakers at testings. 39. The Undertakers may, if they think fit, on each occasion of the testing of any main or service line, or the testing or inspection of any instruments of the Undertakers by any electric inspector, be represented by some officer or other agent, but such officer or agent shall not interfere with the testing or inspection [in most of the Orders this clause concludes with the following words:—Unless such officer or agent shall have reasonable ground for apprehending that the mode of test or inspection adopted will injure the main, instruments, or other apparatus, or interfere with the supply of electricity to the public.]

Expenses of testing. 40. All expenses of testing by an electric inspector, including such reasonable fees to the electric inspector as may from time to time be prescribed in that behalf by the local authority, with the approval of the Board of Trade, shall be paid by the Undertakers, unless the report of the electric inspector, or, in the case of an appeal, the decision of the Board of Trade, shows that the local authority or any body or person supplied with energy was guilty of any default or negligence; and in such case the expenses of the testing, including such fees as aforesaid, shall be ascertained by a court of summary jurisdiction and paid by such local authority, body, or person as the court shall direct. [Previously the Undertakers paid only in cases where default was proved.]

Undertakers to give facilities for testing. 41. The Undertakers shall afford all facilities for the proper execution of this Order with respect to testing and the readings and inspection of instruments, and shall comply with all the requirements of or under this Order in that behalf; and in case the Undetrakers make default in complying with any of the provisions of this section they shall be liable to a penalty not exceeding five pounds, and in the case of a continuing offence to a further penalty not exceeding one pound for every day after the first day during which such offence continues.

Remedying of defects in mains, &c. [*New Clause.*]—42. If at any time it appears to the Board of Trade that any mains, electric lines, or works of the Undertakers are defective and not in accordance with the regulations and conditions subject to which the Undertakers are for the time being authorised to supply energy under this License, the Board of Trade may, by order in writing, require the Undertakers to remedy such defect so as to comply with such regulations and conditions within such period as may be therein limited in that behalf, and if the Undertakers make default in remedying such defect within the time so limited they shall be liable to a penalty not exceeding twenty pounds for every day during which such default continues. Provided that if such defect is, in the opinion of the Board of Trade, dangerous to public safety, they may also by any such Order as aforesaid forbid the use of such main, electric line, or work as from such date as may be specified in that behalf until the defect is remedied, and if the Undertakers make use of any such main, electric line, or work while the use thereof is so forbidden they shall be liable to a penalty not exceeding one hundred pounds for every day during which such user continues.

The two following clauses, which appeared in the Chelsea Act and in most of the recent draft Orders, are now omitted:—

Mode of testing. Notice shall be given to the Undertakers before the commencement of any testing by an electric inspector, and such testing shall be carried out at such suitable hours as, in the opinion of such inspector, will least interfere with the supply of electricity by the Undertakers, and in such manner as such inspector may think expedient, but except under the provisions of a special Order in that behalf made by the Board of Trade, he shall not be entitled to have access to or interfere with the mains of the Undertakers at any points other than those at which the Undertakers have reserved for themselves access to the said mains: Provided that the Undertakers shall not be held responsible for any interruption in the supply of electricity which may be occasioned by

Digitized by Google

or required by such inspector for the purpose of any such testing as aforesaid.

Undertakers may test instruments of local authority. The Undertakers shall have the right to have access at all reasonable times to such instruments for the sake of testing the same and ascertaining if the same are in order, and may require the local authority forthwith to have the same put in order in case they are not so.

SUPPLY.

The distance up to which the Undertaker is bound to extend service wires, free of charge is increased from 30 to 60 feet.

The clause relating to inspection of an occupier's fittings by the Undertakers' agents has been cut down to the following dimensions :—

. . . . Provided also that the Undertakers shall not be compelled to give a supply of energy to any premises unless they are reasonably satisfied that the electric lines, fittings, and works therein are in good order and condition, and not calculated to affect injuriously the use of energy by the Undertakers or by other persons.

PRICE.

The second paragraph of the following clause is new :—

Maximum prices. 48. The prices to be charged by the Undertakers for energy supplied by them shall not exceed those stated in the Fourth Schedule.

Provided that if the County Council, the local authority, or the Undertakers, shall, at any time after the expiration of seven years after the commencement of this Order, make a representation to the Board of Trade that the prices or methods of charge stated in the said schedule ought to be altered, the Board of Trade, after such inquiry as they may think fit, may make an Order varying the prices or methods of charge stated in the said schedule or substituting other prices or methods of charge in lieu thereof, and the prices or methods of charge so varied or substituted shall have effect on and after such day as may be mentioned in the Order, as if they had been stated in the said schedule. Provided also, that the prices and methods of charge for the time being in force may be altered in like manner at any time after the expiration of any or every period of seven years after the same were last altered.

The schedule provides that—

Where the Undertakers charge any consumer by the actual quantity of energy supplied to him, they shall be entitled to charge him at the following rates per quarter :—For any quantity up to twenty units, thirteen shillings and fourpence ; and for each unit over twenty units, eightpence.

METERS.

The following are the principal clauses relating to meters; they have not undergone much alteration :—

Meters to be used except by agreement. 51. The energy supplied by the Undertakers to any ordinary consumer under this Order, or the electrical quantity contained in such supply (according to the method by which the Undertakers elect to charge), in this Order referred to as "the value of the supply," shall, except as otherwise agreed between such consumer and the Undertakers, be ascertained by means of an appropriate meter duly certified under the provisions of this Order.

Meter to be certified. 52. A meter shall be considered to be duly certified under the provisions of this Order if it be certified by an electric inspector appointed under this Order to be of some construction and pattern, and to have been fixed and to have been connected with the service lines in some manner approved of by the Board of Trade, and to be a correct meter ; and every such meter is in this Order referred to as a "certified meter"; provided that where any alteration is made in any certified meter, or where any such meter is unfixed or disconnected from the service lines, such meter shall cease to be a certified meter unless and until it be again certified as a certified meter under the provisions of this Order

Fees for certifying meters. 53. Every electric inspector who may be required by the Undertakers or by any consumer to examine any meter for the purpose of certifying the same as a certified meter under the provisions of this Order shall be entitled to demand from the Undertakers or consumer so requiring him and to be paid such fees as may from time to time be determined in that behalf by the County Council with the approval of the Board of Trade, before commencing such examination, and every electric inspector shall, upon being required so to do by the Undertakers or any such consumer as aforesaid, examine any meter situate within the district for which he is appointed if such fees are offered to him as aforesaid, and shall certify the same as a certified meter if he considers it entitled to be so certified.

Undertakers to supply meters if required to do so. 54. Where the value of the supply is under this Order required to be ascertained by means of an appropriate meter, the Undertakers shall, if required so to do by the consumer, supply him with an appropriate meter . . . . and procure such meter to be duly certified . . . .

Meters not to be connected or disconnected without notice. 55. No consumer shall connect any meter used or to be used under this Order for ascertaining the value of the supply with any electric line through which energy is supplied by the Undertakers, or disconnect any such meter from any such electric line, unless he has given to the Undertakers not less than forty-eight hours' notice in writing of his intention so to do, and if any person acts in contravention of this section he shall be liable for each offence to a penalty not exceeding forty shillings.

Consumer to keep his meter in proper order. 56. Every consumer of energy supplied by the Undertakers shall at all times at his own expense keep all meters belonging to him, whereby the value of the supply is under this Order to be ascertained, in proper order for correctly registering such value, and in default of his so doing the Undertakers may cease to supply energy through such meter.

The Undertakers shall have access to and be at liberty to take off, remove, test, inspect, and replace any such meter at all reasonable times, provided that all reasonable expenses of and incident to any such taking off, removing, testing, inspecting, and replacing, and the procuring such meter to be again duly certified where such re-certifying is thereby rendered necessary, shall, if the meter be found to be not in proper order, be paid by the consumer, but if the same be in proper order all expenses connected therewith shall be paid by the Undertakers. . . .

Undertakers to keep meter let for hire in repair. 58. The Undertakers shall, unless the agreement of hire otherwise provides, at all times, at their own expense, keep all meters let for hire by them to any consumer, whereby the value of the supply is ascertained, in proper order for correctly registering such value, and in default of their so doing the consumer shall not be liable to pay rent for the same during such time as such default continues. The Undertakers shall, for the purposes aforesaid, have access to and be at liberty to remove, test, inspect, and replace any such meter at all reasonable times : Provided that the expenses of procuring any such meter to be again duly certified where such re-certifying is thereby rendered necessary shall be paid by the Undertakers.

Differences as to correctness of meter to be settled by Inspector. 59. If any difference arises between any consumer and the Undertakers as to whether any meter whereby the value of the supply is ascertained (whether belonging to such consumer or the Undertakers), is or is not in proper order for correctly registering such value, or as to whether such value has been correctly registered in any case by any meter, such difference shall be determined upon the application of either party by an electric inspector, or, where the County Council are the consumers, by an inspector to be appointed by the Board of Trade, who shall also order by which of the parties the costs of the proceedings before him shall be paid, and the decision of such inspector shall be final and binding on all parties. Subject as aforesaid, the register of the meter shall be conclusive evidence in the absence of fraud of the value of the supply.

LABORATORY NOTES ON ALTERNATING-CURRENT CIRCUITS.*

BY PROFS. W. E. AYRTON, F.R.S., AND JOHN PERRY, F.R.S.

At the last meeting, Prof. Perry and I received an urgent request from your indefatigable secretary to read a Paper at this meeting, as unforeseen circumstances had prevented the authors of two other Papers from sending them in in time. We pointed out that we had no Paper ready ; we were, however, urged to do something, and it occurred to us that possibly some short account of a few of the experiments that some of the students of the Central Institution are at present engaged upon might be of interest to the members.

You are of course all aware that, when you are dealing with varying currents, self-induction is of importance ; indeed, if the alternations are only sufficiently rapid, self-induction completely replaces resistance, the resistance becomes entirely unimportant, and self-induction is all-important. In the case, for instance, of a well-made transformer, the resistance of the primary circuit may be practically neglected altogether, and all that you have to consider in order to determine what current will flow through the primary circuit for a given mean potential difference at the terminals is the effective coefficient of self-induction. In spite of the importance that self-induction possesses, and in spite of the fact that the largest distributions of electric power in this and in other countries are carried out by means of alternating currents, there is a wonderful amount of ignorance possessed by us all as to what is the coefficient of self-induction of any particular circuit. We have, in fact, no instinctive feeling whatever as to the value of the self-induction of a coil or a circuit when we see it. Some time ago we were asked by a well-known physicist whether we could tell him what was the self-induction of a Thompson reflecting galvanometer of the ordinary form, having about 7,000 ohms resistance. He said, "I am not particular to 50 per cent., or even 100 per cent., but can you give me any sort of idea as to what it is? Is it, for example, to be measured in centimetres or in miles? and is it a large number of miles or a small number of centimetres?" Well, that impressed upon us how little was any instinctive feeling as to

* Extract from the *Journal* of the Institution of Electrical Engineers Part 79, Vol. XVIII.

Digitized by Google

the magnitude of the coefficient of self-induction of any particular coil called into existence by the appearance of the coil.

As an example, here is a coil wound so that you can see the number of layers, as well as the number of convolutions in each layer. The wire is thick, so that the total number of convolutions can be easily counted, and is seen to be 600. Now, although there is no iron in this core, and although the windings are practically symmetrical, we think that probably no single person in this room can say what is even the approximate value of its self-induction. Were we to tell you that the resistance of this coil were a megohm or a microhm, you would smile, because your experience tells you that the resistance must be of the order of a few ohms. As a matter of fact it is 1·34 ohm. Possibly you could not say from merely looking at the coil whether its resistance was half an ohm or 5 ohms, but if there be no discontinuity nor short circuit you are perfectly certain that a megohm is far above the true value and a microhm far below. But if we were to tell you that its self-induction was a million miles, not a single brow would be raised in astonishment; or if we were to state that it was about 20 yards, you would receive that statement with perfect equanimity; or even if we were to say that it is about 100 miles you would not smile—well, you ought not to smile in that case, for it is about 100 miles, being in reality 92 miles.

Now, how have we got this clear notion with reference to resistance? Obviously by a large number of measurements having been made, by having had to find out what was the resistance of all sorts of lengths of wires and of coils of various sizes and shapes, and therefore we know, from a sort of instinct which has grown up as the result of a large number of measurements, what is roughly the resistance of any particular wire when we see it. It therefore seemed to us that it might be of some interest to you to have the results that have been obtained by various students as to what are the actual coefficients of self-induction of some simple circuits.

The experiments have been made by various groups of students under the charge of Mr. Sumpner; in fact, for some time past, scarcely a coil has been allowed to remain peaceably at rest in our laboratory, but it has been operated on, and its coefficient of self-induction measured. Hence our students are just beginning to acquire that instinctive feeling of which we have spoken, regarding the magnitude of the self-induction of different circuits, and it is our desire to go a little way this evening towards imparting that feeling to you.

First, of course, we must be familiar with the practical unit of self-induction. We should like to be able to say that of course you are all familiar with it, but in view of recent experience we fear that that would be too great an assumption; for only quite recently, at a meeting of the Institution of Civil Engineers, a very large mistake was made by a well-known electrical engineer regarding the magnitude of the unit of self-induction—a mistake which, we pointed out at the time, was very like that of confusing the distance between here and Charing-cross, which is about a mile, with the distance from here to the sun, which is about 100,000,000 miles. The practical unit of self-induction is $99{,}777 \times 10^4$ centimetres; it is not exactly the earth's quadrant, in consequence of the legal ohm not being exactly the intended or true ohm, and therefore, if you want the equation

$$r\,C + L\frac{d\,C}{dt} = E$$

to be true, where r is in ohms, C in amperes, and E in volts, L must be expressed in a unit which is $99{,}777 \times 10^4$ centimetres, about 6,200 miles.

For want of a better name, we suggested some few years ago that the name "secohm" should be employed for this unit, it being of course a second × an ohm, so that a secohm is really $99{,}777 \times 10^4$ centimetres, or about 6,200 miles, or two-hundredths of a secohm is rather more than 300 miles.

When making that suggestion, we showed you an arrangement, which we called a secohmmeter, for enabling the coefficients of self-induction to be measured with the same facility that you have been accustomed to measure an ordinary resistance with a Wheatstone's bridge. Of course, self-induction only shows its effect when currents are varied. You cannot, of course, measure it by steady currents; but by performing certain operations which were explained to you some two years ago you are able to make the measurements with alternating currents or varying currents nearly as easily as you are accustomed to measure resistances by the use of steady currents.

In the secohmmeter that we devised the operation that was performed was this: The battery circuit was alternately made and broken, and during one of these operations—say, during the make of the battery circuit—the galvanometer was rendered inoperative by being short-circuited, so that during every break of that battery circuit the battery was operative, while during every make the galvanometer ceased to be operative. In that way the effect of self-induction was apparently to increase the resistance of a particular circuit by a definite amount, depending on the speed, and from the apparent increase of resistance and the speed the coefficient of self-induction was determined. Since then we have made various alterations in the instrument. One improvement was a very obvious one—to reverse the battery instead of making and breaking the battery circuit, and lastly, to reverse the galvanometer instead of short-circuiting it; so that, at present, with the latest form of the secohmmeter we alternately reverse the battery circuit and the galvanometer circuit, and, as four reversals of each circuit occur for each rotation of the commutator spindle, the sensibility of the latest form is eight times as great as the first form that we had the honour of bringing before the Society two years ago.

The commutators can be driven at one or other of two speeds relatively to that of the driving handle. With one arrangement there are rather more than eight reversals of both the galvanometer and of the battery for one revolution of the handle, and with the other twenty-four reversals of each for one revolution o the handle. The apparatus is so constructed that the speed of the fly-wheel remains the same relatively to that of the handle, whatever speed ratio be employed, and hence the same uniformity of speed can be obtained with either speed ratio. The secohmmeter can be conveniently driven by hand so as to obtain a constant speed of reversal varying from 300 to 6,000 reversals per minute of both the galvanometer and the battery.

To shift from one speed ratio to the other, press down the end of the locking lever at the right of the secohmmeter, and slightly push in or pull out the handle, turning it slightly to assist the toothed wheels engaging properly; when engaged, let go the end of the locking lever.

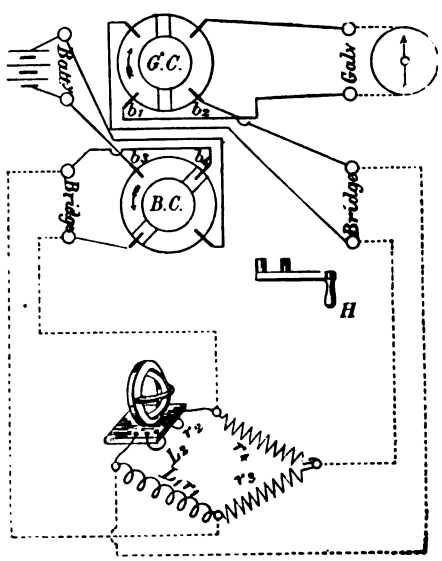

Fig 1.

With the original form of the instrument we proposed to use a speed indicator attached to the rotating spindle, but we pointed out that in some cases it would be desirable to dispense with the speed indicator, especially in view of the difficulty that exists in getting a good cheap speed-indicator; and so most of the measurements that we have to bring before you to-night have not been made in accordance with the first method. We proceeded, not by comparing the coefficient of self-induction in terms of a resistance and a time, but by comparing one coefficient of self-induction with another. You know, of course, if you have a Wheatstone's bridge (Fig. 1) with two wires possessing certain resistances r_1, r_2, and coefficients of self-induction L_1 and L_2, and two other wires possessing resistances r_3 and r_4, but no self-induction, that if you first balance for steady; that is, satisfy the equation

$$\frac{r_1}{r_2} = \frac{r_3}{r_4},$$

you will also have balance for varying currents if in addition you make

$$\frac{L_1}{L_2} = \frac{r_3}{r_4}.$$

The second equation can be fulfilled without disturbing the resistances—that is, without altering the equality of the resistance ratios—if one of the arms contains an apparatus of adjustable self-induction; and further, if the value of self-induction of this apparatus can be read off in secohms for each position of its adjustment we can at once use the secohmmeter for the measurement of a self-induction without the use of a speed indicator.

Digitized by Google

In Fig. 1 B C is the commutator for periodically reversing the battery connections, and G C that for periodically reversing the galvanometer connections, the thick lines in the figure representing permanent connections in the secohmmeter itself, and the dotted lines connections temporarily made outside it. When making such a comparison between an unknown and a known coefficient of self-induction, the speed at which the secohmmeter handle, H, is driven need not be known, but the greater the speed the more sensitive the test; the rate of reversal must not, however, be too great for the currents to reach their steady values between two consecutive reversals.

The variable standard of self-induction that we have been employing is a modification of that used by Prof. Hughes and by Lord Rayleigh, and consists of two coils whose planes may be made to have any angle with one another. The speciality of our apparatus is that we have determined the exact value in secohms of the self-induction of the arrangement for various positions of the coils relatively to one another. The values are recorded on the dial fixed to the larger coil, and over which moves the pointer attached to the smaller coils. The instrument thus constitutes a direct-reading variable standard of self-induction.

The wire on both coils is of platinoid, so that the variation of resistance by temperature is practically negligible. The smaller and movable bobbin, which we call A, is wound with 299½ turns; the larger stationary bobbin with two coils, one of 49 turns, which we will call B, and the other of 147 turns, called C. B and C may be used separately or together, so as to help one another, or so as to oppose one another. There are, therefore, four combinations, A and B, A and B − C, A and C, A and B + C, and with each of these arrangements the smaller coil may be turned round through 180deg. The range of the instrument is—

A and B	steadily increasing self-induction from	0·0135 to 0·0175	secohm.
A ,, B − C	,,	0·0157 ,, 0·0229	,,
A ,, C	,,	0·0171 ,, 0·0283	,,
A ,, B + C	,,	0·0215 ,, 0·0365	,,

The total adjustable range is thus from 0·01356 to 0·0365 secohm, or from about 84 miles to 226 miles. It will be observed that the various component ranges overlap one another fully, so that many of the values can be produced with two arrangements, which is convenient for the purpose of checking the accuracy of a measurement. The smallest coefficient of self-induction that can be obtained with the particular standard is by the use of coil B alone, which corresponds with 0·00096 secohm.

The apparatus therefore constitutes a direct-reading secohm standard. Although the coefficient of self-induction of the standard can only be made to have successively progressive values from 0·0135 to 0·0365 secohm, coefficients of self-induction which do not lie between this limit can be measured: for example, suppose the unknown self-induction L_1 of a coil of resistance r_1 ohms be about 0·5 secohm, then we add a resistance r to r_1, so that

$$\frac{r_1+r}{r_2}=\frac{r_3}{r_4}=20, \text{ say,}$$

in which case balance for varying currrents will be obtained when

$$L_1=20\,L_2;$$

and since $20\,L_2$ varies between 0·27 and 0·73 secohm, these limits include 0·5 secohm, and therefore balance can be obtained on rotating the secohmmeter.

The following are some of the results that the students, under the guidance of Mr. Sumpner, have obtained, using the secohmmeter and the adjustable secohm standard just described:—

Coil wound with copper wire 34 millions in diameter, covered to about 48 millions, consisting of 48 layers with 13 convolutions in each layer, wound on a wooden core 2in. thick and 4in. long,

$$L=0{\cdot}0147 \text{ secohm, } r=1{\cdot}34 \text{ ohm, } \frac{L}{r}=0{\cdot}011 \text{ second;}$$

that is, the "time-constant" of this coil is 0·011 second, which is the time required for any current to rise to 0·6321 of its maximum value after it is started in the coil by an application of a fixed P.D. between the ends of the coil.*

Single coils of an ordinary Morse receiver, iron core about 0·31in. thick and 3in. long, outside diameter of coil 0·94in.,

$$L=0{\cdot}0936 \text{ secohm, } r=32 \text{ ohms.}$$

Another single coil of an ordinary Morse receiver, iron core about 0·31in. thick and 3in. long, outside diameter of coil 1·25in.,

$$L=0{\cdot}444 \text{ secohm, } r=50 \text{ ohms, } \frac{L}{r}=0{\cdot}0089 \text{ second.}$$

The resistance of this second coil is only $\frac{5}{7}$ that of the former, but its self-induction is over four times as great.

[* For further information on this point the student is referred to "Notes on Alternate Currents," by Dr. J. A. Fleming, *The Electrician*, February 24th, 1888, p. 404.]

The two complete coils of a Morse receiver in series, with iron sole-plate and armature—the armature, however, being rather a small one,

$$L=0{\cdot}265, \; r=14 \text{ ohms, } \frac{L}{r}=0{\cdot}018 \text{ second.}$$

Coil of a low-reading magnifying spring voltmeter wound with copper wire on a brass bobbin, no iron inside, length of coil 2·88in., external diameter 3in., diameter of brass bobbin on which wire is wound 0·38in.,

$$L=1{\cdot}462 \text{ secohm, } r=333{\cdot}5 \text{ ohm, } \frac{L}{r}=0{\cdot}0044 \text{ second.}$$

Single coil of an ordinary Thomson's reflecting galvanometer,

$$L=2{\cdot}56 \text{ secohms, } r=2{,}700 \text{ ohms, } \frac{L}{r}=0{\cdot}0007.$$

Single coil of a very high resistance Thomson's reflecting galvanometer, the coil being of about the ordinary size,

$$L=70 \text{ secohms, } r=100{,}000 \text{ ohms, } \frac{L}{r}=0{\cdot}001.$$

Comparing these two last results, we see that the ratio of the self-induction is about the same as the ratio of the resistances, which is correct, as each ratio is proportional to the square of the number of turns of wire when the coils are of the same size and shape. Hence the time-constants are about the same.

An ordinary Ruhmkorff induction coil intended to give a 2-inch spark,

Secondary coil, $L=51{\cdot}2$ secohms, $r=5{,}700$ ohms,

co-efficient of mutual induction, 0·46 secohm.

Ferranti dynamo intended to give 200 volts and 40 amperes,

Armature, $L=0{\cdot}0013$ secohm for one phase,

$=0{\cdot}0011$,, for another phase,

when no current is passing through the field-magnets.

Field-magnets in series $L=0{\cdot}61$ secohm for a small excitation, $r=3$ ohms.

Mather and Platt shunt dynamo, intended to give 100 volts and 35 amperes:

Armature from brush to brush,

$L=0{\cdot}005$ secohm, $r=0{\cdot}215$ ohm.

Field-magnets in series,

$L=13{\cdot}6$ secohms for a small excitation, $r=44$ ohms.

When there is iron in a coil the value of the self-induction depends, of course, on the strength of the current employed when making the observation, and on the way in which this current is varied for determining the self-induction. This will be found very fully worked out, with numerous experimental illustrations, in a Paper by Mr. Sumpner, "On the Variation of the Coefficients of Induction" (*Proc.* Phys. Soc., Vol. IX., Part III., for July, 1888). The following are illustrations of the sort of results obtained:—

Experiments on the Self-Induction of a Kapp and Snell 2 horse-power Transformer.

Through one of the circuits of the transformer of approximate resistance 0·07 ohm a current was passed, which was made to have successively the values shown in the Table on next page. On changing its value great care was taken that the change was steadily in one direction without any fluctuations. The self-induction of the other circuit of the transformer of approximate resistance 0·14 ohm was measured in two distinct ways. With the first method the secohmmeter was employed to rapidly alternate a small current of 0·01 ampere through this circuit, while with the second method the self-induction of this circuit was measured by starting a small current of 0·037 ampere through this circuit. After stopping this current the iron was made to go through the complete magnetic cycle before making the next observation or even repeating the former. For instance, supposing the previous measurement was made by starting a current of 0·037 ampere through the one circuit when the steady current through the other circuit was −2 amperes, then on stopping the current of 0·037 ampere the current through the other circuit was first increased up to +10 amperes, then diminished to −10 amperes, and lastly increased up to −1 ampere, for which value the next observation was made.

As has been already pointed out, the presence of iron in a circuit causes the self-induction of that circuit to have very different values; and, further, it causes the value of the self-induction to depend on the rate on which any particular change in the magnetic induction is effected. For example, if the current through one circuit of the transformer be kept quite constant, and the secohmmeter be used to alternate a definite small current through the other circuit, the value of the cyclical self-induction diminishes somewhat as the speed of alternation is increased.

When we had the honour of first bringing the secohmmeter to your notice in 1887, we exhibited certain curves (Fig. 3, p. 307, *Jour. Soc. Tel. Eng.*, Part 67, Vol. XVI., 1887) showing the apparent increase of resistance of a circuit containing no iron when the secohmmeter was turned at different speeds, and certain other curves (Fig. 4, page 310) for the apparent increase of resistance when an iron core was inserted in the coil. The first set of curves are straight lines, while the second show a distinct curvature. This curvature we attributed at the time to the fact that with high speeds of the secohmmeter the time-constant of the circuit when the iron core was inserted was too large for the current to reach its steady value when the battery circuit was closed, or for the current to die away when it was opened. But on Mr. Sumpner's subsequently attacking this subject both experimentally and theoretically, he found that the increase of the time-constant produced by the insertion of the iron was not sufficient to explain the large amount of bending of the curves. Hence we concluded at the beginning of 1888 that the bending was mainly due to a magnetic lag. At about the same time we obtained evidence that when the speed of the secohmmeter was *very great*, and the lead very small, the insertion of the iron core in a coil actually diminished the self-induction of the circuit—a result that we feared at the time must be due to some defect in the coil, but which the recent investigations of Dr. Lodge now show to be quite possible. This subject we are at present investigating further.

Some time ago we drew attention to the fact that the accuracy of the measurement by means of a wattmeter of the power given by an alternate current to a circuit possessing self-induction depended on the relative values of the time-constant of the fine-wire circuit of the wattmeter and the time-constant of the circuit the power given to which it was desired to measure.

Our result was criticised by Mr. Blathy in *The Electrician* for April 6th, 1888, who made certain calculations regarding the use of the wattmeter constructed by Messrs. Ganz and Co., tending to show that the correction pointed out by ourselves was an unimportant one. We take the opportunity of drawing Mr. Blathy's attention to the fact that in his calculations he has underestimated the value of the self-induction of the suspended coil, and—what is equally important—neglected altogether the self-induction of the so-called non-inductive portion of the fine-wire circuit. Taking the actual specimen of the wattmeter we possess, we find that the suspended coil of resistance 2 ohms has a self-induction 0·00042 secohm. This is about twice what Mr. Blathy allows for it. Further, two of our students—Messrs. Lamb and E. W. Smith—on making a calculation as to the self-induction of the very carefully *doubly-wound* resistance coil of some 980 ohms which is placed in the fine-wire circuit, find that it is 0·00025 secohm, which is more than half the value of the inductive coil And if, in the hypothetical case taken by Mr. Blathy, a *doubly-wound* resistance coil of 100,000 ohms be employed, made of the same wire as is used in the coil of 980 ohms—and this would be necessary, since, the suspended coil remaining the same, the current-density in the high-resistance circuit must remain constant—they find that the self-inductance of the *doubly-wound* resistance will be 0·025 secohm ; so that the self-induction of the high-resistance circuit will be about one hundred times as great as is supposed by Mr. Blathy.

For the purpose of enabling practical men to calculate the self-induction of *doubly-wound* coils made of conducting wire of diameter *d*, covered to a diameter D, and placed parallel to one another, with their insulating coverings in contact, we give the following formula :—

$$\text{L, in secohms, } = \frac{422 \times \log_{10} \frac{D}{d} + 173}{10^9}$$

× total length of going and return wire in yards.

(To be continued.)

THE POST OFFICE AND THE TELEPHONE COMPANIES.

The following letter has been addressed by the Post Office to the United Telephone Company, in continuation of the correspondence already published :—

General Post Office, London, June 21.

Sir : I am directed by the Postmaster-General to acknowledge the receipt of your letter of the 14th inst. replying to my communication of the 4th on the subject of the amalgamation of the telephone companies.

Mr. Raikes cannot admit that there is any room for controversy on the statement that the amalgamation was not contemplated by the Department, and he observes that, as regards the companies themselves, so far from its being shown that amalgamation was in contemplation when the licenses were issued, it is now expressly admitted that it was the policy of the United Telephone Company to parcel out the country amongst subsidiary companies and to confine the operations of these companies to particular districts.

Both by the companies and by the Department it was expected that here and there the companies would purchase some small exchange established by local enterprise, and also that they would occasionally erect a line and sell it outright to the user, instead of leasing it on an annual rental.

The clause to which you refer provides that on such transactions the Department shall not claim royalty. The clause was drawn not by the solicitor to the Department, but by the solicitor of the companies, whose object, as then avowed, was to protect the companies against a double payment of royalty. It had nothing to do with the question of an amalgamation of the United Telephone Company with its subsidiary companies, and cannot be regarded as evidence of amalgamation having been in contemplation.

The Postmaster-General does not, consequently, see any ground for departing from the views expressed in my letter of the 4th inst.

Mr. Raikes must decline at this moment to be drawn into any further controversy with the United Telephone Company upon this question, although he has felt it his duty to make them and the public acquainted with the views which he entertains regarding the projected amalgamation.

I am, Sir, your obedient servant,

S. Arthur Blackwood.

The Secretary, United Telephone Company.

The Electrician.

Published every Friday. Price Fourpence: Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

THE MODEL ORDER AND ELECTRIC LIGHTING INSPECTORS.

Beyond question the most important feature of the "Model Form of a Provisional Order for a Metropolitan Area" is to be found in the relation which it establishes, or seeks to establish, betwixt the Supply Companies on the one hand and the County Council, the Local Authorities, and the Board of Trade upon the other. As the inheritors of the duties and responsibilities of the late Metropolitan Board of Works it was necessary that the County Council should henceforth occupy a prominent position in all Orders relating to the Metropolitan area; but we are unable to consider it either necessary or wise, and we are even surprised to learn that it is within the power of the Board of Trade, to transfer to the Council *en bloc* the important duties which have hitherto been assigned to the local authorities, as well as certain other powers which had been rightly reserved to itself. In future no overhead wire is to be erected in the Metropolis (for electric lighting purposes) without the consent of the County Council. The County Council is to appoint "competent and impartial persons to be electric inspectors for the purpose of inspecting electric lines and works, *and of certifying meters.*" The County Council (and not as hitherto the Board of Trade) is to determine the number of testing stations which the Undertakers will be required to erect at their own expense. (We may add parenthetically, as showing the beautiful simplicity and perfection of the arrangements, that the instruments are to be approved by the Board of Trade, that they are to be used by the County Council's Inspector, that it is expressly provided the Undertakers may look on, but must not interfere, even if the Inspector breaks down the circuit, and finally, that it is provided that any dispute arising out of the action of the Inspector is to be settled, not by the Board of Trade, but by arbitration). Once more, as indicating the singular and the almost painful subservience to the County Council which for some inscrutable reason the Board of Trade seems bent on showing whenever opportunity arises, we may instance the following. Hitherto it has always been customary to insert a clause providing that if the local authority fail to appoint an Inspector, *or if the duties devolving upon the Inspector be imperfectly attended to by the local authority*, the Board shall, if it sees fit, itself appoint a competent and impartial person to

Digitized by Google

the post. This provision we regard as a valuable safeguard; but in the Model Order, now that the local authority has been superseded by the County Council, the sentence italicised above is altogether omitted!

We have already had occasion to observe—and we believe that in so doing we are expressing the opinion of every competent and impartial person who is acquainted with the real position of Central Station electric lighting—that whilst it will ultimately be a great and obvious advantage to have the administration of the Electric Lighting Acts in the metropolitan area as far as possible consolidated under one authority, yet for the time being, and until the business has got into something like working order, it is for many reasons preferable that the existing local authorities should continue to exercise their discretion under the paternal oversight of the Board of Trade. The varied experience which would be gained under the administration of the Vestries would, at the end of a couple of years or so, form an invaluable fund of information from which the County Council would readily be enabled to frame a wise and sensible policy. In short, the Council will at that time be in a position to know something of the nature of the business which they are undertaking, whilst at present they are absolutely in the dark, and although it is true that the Vestries are not very much more enlightened, yet if they blunder it will be on a smaller scale, and they will probably have no difficulty in finding examples in other districts by which to be guided. We are strongly of opinion that it is to be desired that the Board should rather extend the limits of its supervision than that it should divest itself of its powers in favour of the County Council, or of any one else. In omitting all mention of the Electric Lighting Acts in the Act which created the County Council, it has hitherto been believed that it was the distinct intention of Parliament to allow some time to pass away and experience to be gained before the Council was entrusted with these powers. It is, therefore, somewhat of a revelation to us to learn that the matter rests wholly at the discretion of the Board of Trade.

There is, however, another question—one of admitted difficulty—in which as touching the whole Kingdom the interests at stake are of even more importance, and on which we think that the policy of the Board of Trade from the very beginning demands reconsideration. We refer to the duties and emoluments which are assigned to the local Inspectors. These persons are to test mains for insulation and conductivity; "if and when required to do so by any person supplied with energy by the Undertakers," they are similarly to test the service lines; they are to examine and record the readings of the instruments to be set up by the Undertakers at the Testing Stations, and they are to furnish reports to the Undertakers, as well as to the "authority or person by whom he was required to make such testing," whilst it is provided that the Board of Trade shall decide any dispute which may arise out of such report. So far we raise no objection whatever; no difficulty need be apprehended as to the supply of men fully able to carry out these simple duties, nor should there be any great difficulty as to their instrumental equipment, though at the same time we will remark in passing that the testing (and consequent disconnecting) of a service line, except in case of extreme need, is a proceeding which may be supposed to recommend itself to a County Councillor more forcibly than to an electrical engineer. But we do strongly object to the system of fees which are to be paid to the Inspector (either for his own behoof or for that of the County Council), especially since in certain cases the Undertakers are called upon to pay whether the test proves them to have been in default or not. It even appears that the Inspector may carry out certain tests as often as he pleases, claiming his fee every time. All this urgently demands revision; in its present shape it seems to us flatly unworkable. The Inspector should receive a definite salary, and the Undertakers should contribute nothing save in the shape of fines for default.

There is, moreover, one other duty which the Inspector is to be called upon to perform—which is none else than the testing and certifying of meters. Seeing also that a certified meter loses its certificate by the act of disconnection from the mains, and that every meter ought, at least at first, to be retested at the end of twelve months, it is clear that this will form no small portion of the Inspector's business. Now how are these important duties to be performed? We can scarcely suppose that the Board of Trade seriously contemplates the establishment of an electrical standardising laboratory by every local authority throughout the country. We do not know that eventually something of this kind might not be done, or that at the least a considerable number of branches of the chief laboratory will not come to be established. But for the present we are confronted by the fact that the Board of Trade throws the responsibility entirely upon the local authority. It is true that the County Council has already expressed its eager desire to undertake the work, but it is equally true that it has not the least notion of what it is talking about. We are willing to suppose that when the Board of Trade first came to a conclusion upon this point it was acting under the belief that the inspectors might readily be provided with secondary standards, which could be compared with the meters *in situ*. In the case of direct currents, it is, perhaps, conceivable that a conscientious inspector, with plenty of time at his disposal, might carry out such a test with a degree of accuracy not greatly below what is usually deemed sufficient for commercial purposes. But even this concession cannot be made in the case of alternating meters. Moreover, it must not be overlooked that if a meter is to be tested throughout its range—and if not what is the "certificate" worth?—a period of from 6 to 10 hours at least will be necessary for the test. It is useless to waste time in arguing the point further, though much more might easily be said. We believe that the entire profession will agree with us in saying that if travelling inspectors are expected to certify meters the whole system becomes a transparent farce.

ON MODERN VIEWS WITH RESPECT TO THE NATURE OF ELECTRIC CURRENTS.*

BY PROF. H. A. ROWLAND.

(Concluded from page 175.)

So far we have considered the case of alternating electric current in a wire connecting the inner and outer coatings of a Leyden jar. The invention of the telephone, by which sound is carried from one point to another by means of electrical waves, has forced into prominence the subject of these waves. Furthermore, the use of alternating currents for electric lighting brings into play the same phenomenon. Here, again, the difference between a current of water and a current of electricity is very marked. A sound wave, traversing the water in the tube, produces a to-and-fro current of water at any given point. So, in the electrical vibration along a wire, the electricity moves to and fro along it in a manner somewhat similar to the water, but with this difference; the disturbance from the water-motion is confined to the tube, and the oscillation of the water is greatest in the centre of the tube, while in the case of the electric current the ether around the wire is disturbed and the oscillation of the current is greatest at the surface of the wire and least in its centre. The oscillations in the water take place in the tube without reference to the matter outside the tube, whereas the electric oscillations in the wire are entirely dependent on the surrounding space, and the velocity of the propagation is nearly independent of the nature of the wire, provided it is a good conductor.

* A lecture given at the College of the City of New York, May 22, 1889, before the American Institute of Electrical Engineers.

Digitized by Google

We have then in the case of electrical waves along a wire a disturbance outside the wire and a current within it, and the equations of Maxwell allow us to ca'culate these with perfect accuracy and give all the laws with respect to them.

We thus find that the velocity of propagation of the waves along a wire, hung far away from other bodies and made of good conducting material, is that of light, or 185,000 miles per second, but when it is hung near any conducting matter, like the earth, or inclosed in a cable and sunk into the sea, the velocity becomes much less. When hung in space, away from other bodies, it forms, as it were, the core of a system of waves in the ether, the amplitude of the disturbance becoming less and less as we move away from the wire. But the most curious fact is that the electric current penetrates only a short distance into the wire, being mostly confined to the surface, especially where the number of oscillations per second is very great.

The electrical waves at the surface of a conductor are thus, in some respects, very similar to the waves on the surface of water. The greatest motion in the latter case is at the surface, while it diminishes as we pass downwards and soon becomes inappreciable. Furthermore, the depth to which the disturbance penetrates into the water increases with increase of the length of the wave, being confined to very near the surface for very short waves. So the disturbance in the copper penetrates deeper as the waves and the time of oscillation are longer, and the disturbance is more nearly confined to the surface as the waves become shorter. I have recently made the complete calculation with respect to these waves, and have drawn some diagrams to illustrate the penetration of the alternating current into metal cylinders. The right-hand curve, Fig. 1, represents the current at different depths in a copper cylinder 45 centimetres diameter, or an iron one 14⅓ centimetres diameter, traversed by an alternating current with 200 reversals per second. That and the middle curve show us the current at two different instants of time, and show us how the phase changes as we pass

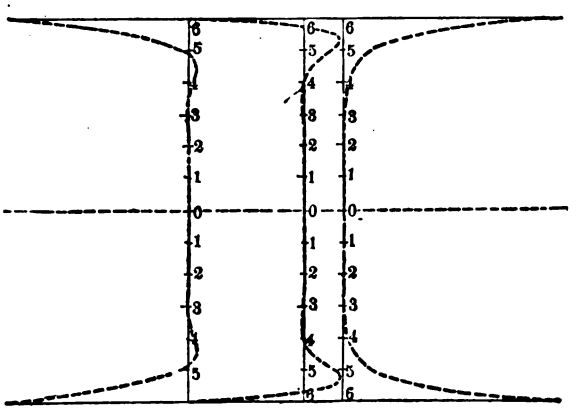

FIG. 1.—Penetration of alternating current in a round solid conductor.

downward into the cylinder. By reference to the middle curve we see that it may be even in the opposite direction in the centre of the cylinder from which it is at the surface. The third figure gives us the amplitude of the current oscillations at different depths, irrespective of the phase, and it shows us that the current at the centre is only about 10 per cent. of that at the surface in this case. The second diagram, Fig. 2, shows us the distribution in the same cylinders when the number of reversals of the current is increased to 1,800 per second. Here we see that the disturbance is almost entirely confined to the surface, for at a depth of only 7 millimetres the disturbance almost entirely vanishes.

There are very many practical applications of these theoretical results for electric currents. The most obvious one is to the case of conductors for the alternating currents used in producing the electric light. We find that when these are larger than about half an inch diameter they should be replaced by a number of conductors less than half an inch diameter, or by strips about quarter of an inch thick, and of any convenient width. But this is a matter to be attended to by the electric light companies.

Prof. Oliver J. Lodge has recently, in the B. A., drawn attention to another application of these results—that is, to lightning rods. Almost since the time of Franklin, there have been those who advocated the making of lightning rods hollow in order to increase the surface for a given amount of copper. We now know that these persons had no reason for their belief, as they simply drew the inference from the fact that electricity at best is on the surface. Neither were the advocates of the solid rods quite correct, for they reasoned from the fact that electricity in a state of steady flow occupies the whole area of the conductor equally. The true theory, we now know, indicates that neither party was entirely correct and that the surface is a very important factor in the case of a current of electricity so sudden as that from a lightning discharge. But increase of surface can best be obtained by multiplying the number of conductors, rather than making them flat or hollow, and, at the same time, Maxwell's principle of inclosing the building within a cage can be carried out. Theory indicates that the current penetrates only one-tenth the distance into iron that it does into copper. As the iron has seven times the resistance of copper, we should need seventy times the surface of iron that we should of copper. Hence I prefer copper wire about a quarter of an inch diameter and nailed directly to the house without insulators, and passing down the four corners, around the eaves and over the roof, for giving protection from lightning in all cases where a metal roof and metal down spouts do not accomplish the same purpose.

Whether the discharge of lightning is oscillatory or not does not enter into the question, provided it is only sufficiently sudden. I have recently solved the mathematical problem of the electric oscillations along a perfectly-conducting wire joining two infinite and perfectly-conducting planes parallel to each other, and find that there is no definite time of oscillation, but that the system is capable of vibrating in any time in which it is originally started. The case of lightning between a cloud of limited extent and the earth along a path through the air of great resistance is a very different problem. Both the cloud and the path of the electricity are poor conductors, which tends to lengthen the time. If I were called on to estimate as nearly as possible what took place in a flash of lightning, I would say that I did not believe that the discharge was always oscillating, but more often consisted of one or more streams of electricity at intervals of a small fraction of a second, each one continuing for not less than $\frac{1}{100000}$ second. An oscillating current with 100,000 reversals per second would penetrate about $\frac{1}{60}$in. into copper and $\frac{1}{600}$in. into iron. The depth for copper would constitute a considerable proportion of a wire ¼in. diameter, and, as there are other considerations to be taken into account, I believe it is scarcely worth while making tubes, or flat strips, for such small sizes.

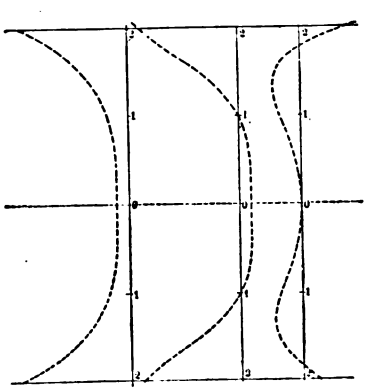

FIG. 2.—Penetration of alternating current in a round solid conductor.

It is almost impossible to draw proper conclusions from experiments on this subject in the laboratory, such as those of Prof. Oliver J. Lodge. The time of oscillation of the current in most pieces of laboratory apparatus is so very small, being often the $\frac{1}{10000000}$ of a second, that entirely wrong inferences may be drawn from them. As the size of the apparatus increases the time of oscillation increases in the same proportion, and changes the whole aspect of the case. I have given $\frac{1}{100000}$ of a second as the shortest time a lightning flash could probably occupy. I strongly suspect it is often much greater, and thus departs even further from the laboratory experiments of Prof. Lodge, who has, however, done very much towards drawing attention to this matter and showing the importance of surface in this case. All shapes of the rod with equal surface are not, however, equally efficient. Thus, the inside surface of a tube does not count at all. Neither do the corrugations on a rod count for the full value of the surface they expose, for the current is not distributed uniformly over the surface; but I have recently proved that rapidly alternating currents are distributed over the surface of very good conductors in the same manner as electricity at rest would be distributed over them, so that the exterior angles and corners possess much more than their share of the current, and corrugations on the wire concentrate the current on the outer angles and diminish it in the hollows. Even a flat strip has more current on the edges than in the centre.

For these reasons, shape, as well as extent of surface, must be taken into account, and strips have not always an advantage over wires for quick discharges.

The fact that the lightning rod is not melted on being struck by lightning is not now considered as any proof that it has done its work properly. It must, as it were, seize upon the discharge, and

Digitized by Google

offer it an easier passage to the earth than any other. Such sudden currents of electricity we have seen to obey very different laws from continuous ones, and their tendency to stick to a conductor and not fly off to other objects depends not only on having them of small resistance, but also on having what we call the self-induction as small as possible. This latter can be diminished by having the lightning rod spread sideways as much as possible, either by rolling it into strips, or better, by making a network of rods over the roof with several connections to the earth at the corners, as I have before described.

Thus we see that the theory of lightning rods, which appeared so simple in the time of Franklin, is to-day a very complicated one and requires for its solution a very complete knowledge of the dynamics of electric currents. In the light of our present knowledge the frequent failure of the old system of rods is no mystery, for I doubt if there are a hundred buildings in the country properly protected from lightning. With our modern advances, perfect protection might be guaranteed in all cases, if expense were no object.

So much for the rod itself, and now let us turn to other portions of the electrical system; for we have seen that, in any case, the conductor is only the core of a disturbance which extends to great distances on all sides. Were the clouds, the earth and the streak of heated air called the lightning flash all perfect conductors; we could calculate the entire disturbance. It might then consist of a series of stationary waves between the two planes, extending indefinitely on all sides, but with gradually decreasing amplitude as we pass away from the centre. The oscillation, once set up, would go on for ever, as there would be no poor conductors to damp them. But when the clouds and the path of the lightning both have very great resistance the energy is very soon converted into heat and the oscillations destroyed. I have given it as my opinion that this is generally the case, and that the oscillations seldom take place, but I may be wrong, as there is little to guide me except guess-work. If they take place, however, we have a ready explanation of what is sometimes called a back stroke of lightning. That is, a man at the other end of the cloud a mile or more distant from the lightning stroke sometimes receives a shock, or a new lightning flash may form at that point and kill him. This may be caused, according to our present theory, by the arrival of the waves of electrical disturbance, which might themselves cause a slight shock, or even overturn the equilibrium then existing, and cause a new electric discharge.

We have now considered the case of oscillations of electricity in a few cases, and can turn to that of steady currents. The closing of an electric current sends etherial waves throughout space, but after the first shock the current flows steadily without producing any more waves. However, the properties of the space around the wire have been permanently altered, as we have already seen. Let us now study these properties more in detail. I have before me a wire in which I can produce a powerful current of electricity, and we have seen that the space around it has been so altered that a delicately-suspended magnetic needle cannot remain quiet in all positions, but stretches itself at right angles to the wire, the north pole tending to revolve around it in one direction and the south pole in the other. This is a very old experiment, but we now regard it as evidence that the properties of the space around the wire have been altered rather than that the wire acts on the magnet from a distance.

Put, now, a plate of glass around the wire, the latter being vertical and the former with its plane horizontal, and pass a powerful current through the wire. On now sprinkling iron filings on the plate they arrange themselves in circles around the wire and thus point out to us the celebrated lines of magnetic force of Faraday. Using two wires with currents in the same direction we get these other curves, and, testing the forces acting on the wire, we find that they are trying to move toward each other.

Again, pass the currents in the opposite directions and we get these other curves and the currents repel each other. If we assume that the lines of force are like rubber bands which tend to shorten in the direction of their length and repel each other sideways, Faraday and Maxwell have shown that all magnetic attraction and repulsions are explained. The property which the presence of the electric current has conferred on the luminiferous ether is then one by which it tends to shorten in one direction and spread out in the other two directions.

We have thus done away with action at a distance, and have accounted for magnetic attraction by a change in the intervening medium as Faraday partly did almost fifty years ago. For this change in the surrounding medium is as much a part of the electric current as anything that goes on within the wire.

To illustrate this tension along the lines of force, I have constructed this model, which represents the section of a coil of wire with a bar of iron within it. The rubber bands represent the lines of force which pass around the coil and through the iron bar, as they have an easier passage through the iron than the air. As we draw the bar down and let it go, you see that it is drawn upward and oscillates around its position of equilibrium until friction brings it to rest. Here, again, I have a coil of wire with an iron bar within it with one end resting on the floor. As we pass the current and the lines of magnetic force form around the coil and pass through the iron, it is lifted upwards, although it weighs 24lb., and oscillates around its position of equilibrium exactly the same as though it were sustained by rubber bands as in the model. The rubber bands in his case are invisible to our eye, but our mental vision pictures them to us as lines of magnetic force in the luminiferous ether drawing the bar upward by their contractile force. This contractile force is no small quantity, as it may amount, in some cases, to one or even two hundred pounds to the square inch, and thus rivals the greatest pressure which we use in our steam engines.

Thus the luminiferous ether is, to-day, a much more important factor in science than the air we breathe. We are constantly surrounded by the two, and the presence of the air is manifest to us all; we feel it, we hear by its aid, and we even see it, under favourable circumstances, and the velocity of its motion as well as the amount of moisture it carries is a constant topic of conversation with mankind at large. The luminiferous ether, on the other hand, eludes all our senses, and it is only with imagination, the eye of the mind, that its presence can be perceived. By its aid in conveying the vibrations we call light, we are enabled to see the world around us, and by its other motions which cause magnetism, the mariner steers his ship through the darkest night when the heavenly bodies are hid from view. When we speak in a telephone, the vibrations of the voice are carried forward to the distant point by waves in the luminiferous ether, there again to be resolved into the sound waves of the air. When we use the electric light to illuminate our streets, it is the luminiferous ether which conveys the energy along the wires as well as transmits it to our eye after it has assumed the form of light. We step upon an electric street-car and feel it driven forward with the power of many horses, and again it is the luminiferous ether whose immense force we have brought under our control and made to serve our purpose, no longer a feeble, uncertain sort of medium, but a mighty power, extending throughout all space and binding the whole universe together, so that it becomes a living unit in which no one portion can be changed without ultimately involving every other portion.

To this, ladies and gentlemen, we have been led by the study of electrical phenomena, and the ideas which I have set forth constitute the most modern views held by physicists with respect to electric currents.

THE ELECTRICAL EXHIBITS AT THE ROYAL AGRICULTURAL SOCIETY'S SHOW AT WINDSOR.

The fiftieth annual exhibition of this Society was opened on Saturday last in Windsor Great Park in fine weather, and will continue open until to-morrow (Saturday). Amongst the numerous exhibitors are most of the well-known engineering firms, but electrical exhibits are conspicuous by their absence—a circumstance greatly to be regretted, as the annual gathering of this Society presents exceptionally good opportunities for bringing before the wealthier classes many articles of an electrical character for inspection and purchase which would otherwise never come under their notice. We feel the less hesitation in saying this as the utmost interest was exhibited in the artistic electric light installation at Messrs. Priestman's Stand (No. 297), which attracted crowds of admiring visitors.

One of the few things electrical on the show ground is Messrs. Immisch's electrical dog-cart (Stand No. 74), which was described and illustrated in *The Electrician* of September 14, 1888. At the Stand of Messrs. Priestman Brothers (No. 297), Messrs. Lea, Sons and Co., of Pengwerne Works, Shrewsbury, have a small electric light installation, and an extremely pleasing exhibit of hammered iron work of exceptionally handsome designs. They show a number of wall brackets, electroliers, and side-lights under the name of "Metalli-Floral Electric Fittings," the beautiful designs of which have only to be seen to be thoroughly appreciated. They are to be congratulated upon their very laudable desire to revive th almost lost art of producing elegant designs in hammered metal. The Acme Electric Works, of Chalk Farm-road, London, at the Griffin Gas Engine Company's Stand (No. 374), and Mr. H. J. Rogers, of Watford Engineering Works (who has an Elwell-Parker plant installed), at Stand No. 293, have small electric light installations; and these seem to exhaust the very limited number of electrical exhibits at the Show.

In the Engineering Section very fine engine and machinery exhibits are made by most of the prominent makers. Messrs. Davey, Paxman and Co. show several of their well-known engines, amongst which is a 16 horse-power compound engine and boiler, fitted with Paxman's patent automatic expansion gear and patent adjustable high-speed governors and feed-pump. Messrs. Robey

Digitized by Google

and Co., of Lincoln, have, at Stand No. 1, several of their well-known engines, fitted with their improved high-speed equilibrium governors. Most conspicuous amongst these is a 12 horse-power compound "Robey" engine and boiler, controlled by Richardson's patent governor and link expansion gear, by which the cut-off can be regulated from ⅛ to ⅞ of the stroke, with only slight variations in load. There is also their well-known type of high-speed vertical engine and dynamo combined, suitable for small electric light installations or for ships' lighting, &c. Messrs. John Fowler and Co., of Leeds, exhibit, at Stand No. 4, a 25 horse-power (nom.) compound engine, specially constructed for driving the electric-light installation at Col. North's mansion at Eltham, Kent. The high-pressure cylinder is 10in. and the low-pressure 16in. in diameter by 20in. stroke, with a speed of 120 revolutions per minute. Both cylinders are fitted with Hartnell's patent automatic expansion gear, controlled by one governor. The fly-wheel is grooved for five 1¼in. ropes, and is 10ft. in diameter. The engine is specially constructed for long runs, and has drop-sight lubricators to all the bearings and sight-feed lubricators on both steam chests We hope to give further particulars of this engine in a future issue. Messrs. Fowler also show an 8 horse-power semi-portable engine and one of Scott's convertible high-speed engines, both suitable for electric-light work, and they have on view some specimens of Tatham's well-known lead-covered wire for telephones and electric light. Messrs. Ransomes, Sims and Jefferies, of the Orwell Works, Ipswich, show a number of engines at Stand No. 275, amongst which is a 10 horse-power compound "undertype" engine and a 16 horse-power long-stroke stationary engine, with patent automatic expansion gear; the latter is a fine specimen of engineering work, and is specially constructed for driving machinery where high efficiency and great regularity of speed is required. At Stand No. 312, Messrs. Marshall, Sons and Co., of Gainsborough, exhibit a 12 horse-power stationary engine, with Hartnell's gear and Marshall's speed indicator, and a number of their well-known portable and traction engines. Messrs. Richard Hornsby and Sons (Limited), of Grantham, exhibit at Stand No. 278 a 10 horse-power "underneath" high-pressure vertical engine, suitable for use where space is limited and where keeping the crank-shaft low down is an advantage; these engines require very little foundation, and are easily removed. Other exhibitors in this section are Messrs. Clayton and Shuttleworth, of Lincoln, who have on view a 12 horse-power compound engine, fitted with Tyrell and Deed's patent governor; Messrs. Ruston, Proctor and Co., of Lincoln; Messrs. E. R. and F. Turner, of Ipswich; Messrs. Weyman and Johnson, of Guildford; Mr. E. S. Hindley, of Bourton, Dorset; Messrs. Charles Burrell and Sons, of Thetford, who show a 16 horse-power "undertype" engine, fitted with automatic expansion gear controlled by the governor, being specially adapted for driving electric-lighting machinery; Messrs. J. and H. Maclaren, of Leeds; Messrs. Woods and Co., of Stowmarket; Messrs. Brown and May, of Devizes; Messrs. Edward Humphries (Limited), of Pershore; Messrs. W. H. Nicholson and Sons, of Newark-on-Trent; Messrs. Farmer, Robey, Clark and Co., of Gainsborough; Messrs. Richmond and Chandler, of Manchester; and Mr. Alfred Dodman, of King's Lynn. The display of engines of all kinds is a very large one, and it is probable that never before were so many on view at one time.

A number of gas-engines are exhibited, amongst which Messrs. Crossley Brothers' well-known "Otto" type occupies a conspicuous place. They show at Stand No. 375 a 9 horse-power horizontal and a 3 horse-power vertical engine with hoist gear attached. This firm has recently substituted for the old-type slide arrangement a tube igniter; they claim that this is a most important improvement and effects a great saving in gas. They have also introduced a new pendulum governor, by means of which strap and wheel are dispensed with. This arrangement is very ingenious and simple. At Stand No. 374 the Griffin Gas Engine Company exhibit a number of their engines, one of which is driving a Royce dynamo at the small but effective electric-light installation of the Acme Electric Works mentioned above. Amongst other exhibitors of gas-engines are Messrs. J. E. H. Andrew and Co., of Redditch, who show the "Stockport" and "Bischoff" engines; the British Gas Engine and Engineering Company (Limited), who have on view the Atkinson "Cycle" engine; the Beck Gas Engine Company, and the Campbell Gas Engine Company.

Oil-engines find a place among the exhibits, the most important being undoubtedly those at Stand No. 297, shown by Messrs. Priestman Bros., of Hull and London. These engines are of the latest type, and comprise a 6 horse-power (nominal) portable engine, the special feature of which is the application of this motive-power to a portable engine, this being its first introduction to the general public. Messrs. Priestman claim that they are able to use common mineral oils with their engines, that no driver is required, and that but little attention is necessary. They have also on view a 4 horse-power (nominal) horizontal engine, which is used to drive a 50-light dynamo for Messrs. Lea, Sons and Co.'s installation of the electric light already referred to. The general design of this engine has recently been much improved as to compactness, &c., and it is now so constructed that every part is easily accessible. A 1 horse-power engine similar to the foregoing is also shown, fitted with an air-compressor mounted upon a sole-plate at the end of the engine and connected directly by gearing. This engine is suitable for pumping, &c. An improved method of supplying electricity for igniting purposes by means of a small storage cell is likewise exhibited, the advantage of which will be readily seen, as the cell will last for about three months without being recharged. Messrs. Priestman inform us that they have orders for a large number of these engines, both for home and export. Another oil-engine is that shown at Stand No. 296 by Mr. J. H. Knight, of Barfield, Farnham, who claims for his engine that it will be found very useful for small electric-light installations or for driving ventilators, it occupying only a small space. We understand that Messrs. Brown and May, of Devizes, will shortly undertake the manufacture of these engines. At Stand No. 295 is an oil-engine made by Mr. G. W. Weatherhogg, of Swinderley, near Lincoln, which is not at work, but for which it is claimed that it is not liable to accident by explosion and is silent and economic in working.

Several turbines are exhibited, conspicuous amongst which are those shown by Mr. C. L. Hett, of Brigg; Mr. H. P. Vacher, of Winchester; Messrs. G. Gilkes and Co., of Kendal; and Mr. C. Cadle, of Wellington Quay, Dublin.

Amongst other exhibitors may be mentioned the Blackman Ventilating Company, who show their well-known ventilating fans; Messrs. W. H. Willcox and Co., of Southwark-street, London, S.E., who have a fine display of engineers' stores, &c.; Messrs. W. F. Dennis and Co., of Leadenhall-street, who show a number of specimens of fencing wire, &c., manufactured by Messrs. Felten and Guilleaume, of Mülheim. There are exhibits of driving bands of all kinds, pulleys, &c., by the best-known makers.

Speaking of the Show as a whole, it is undoubtedly one of the largest and best the Society has ever held, and, with a continuance of fine weather, we have no doubt that the attendance will exceed that at Nottingham last year, when 147,927 visitors were admitted. As mentioned above, the Show will be open to-day (Friday) and to-morrow, and the large number of interesting exhibits of all kinds will well repay a visit.

After the parade of the cattle before their Royal Highnesses the Prince and Princess of Wales and the Royal Family, on Wednesday, His Royal Highness was graciously pleased to order the electric carriage, exhibited by Messrs. Immisch, at Stand No. 74, to be brought before him by a member of the firm, who explained the principle and action of the mode of locomotion. Their Royal Highnesses all appeared greatly interested in the simplicity of the details and in the ease with which the carriage is driven and guided. The motive force was supplied by accumulators from one of Messrs. Immisch's electric launch-charging stations, now lying in the Thames off Windsor.

LEGAL INTELLIGENCE.

King, Brown and Co. v. The Anglo-American Brush Electric Light Corporation (Limited).

JUDGMENT.

LORD TRAYNER, in the Court of Session, on Wednesday, gave judgment in the action by King, Brown and Co., Rosebank Electric Works, Broughton-road, Edinburgh, against the Anglo-American Brush Electric Light Corporation (Limited), 6, York-place, Edinburgh, for the reduction of the defenders' letters patent respecting series-shunt winding.

His LORDSHIP said: The question to be determined in this case is whether Mr. Brush is the inventor of (1) the peculiar form of commutator, and (2) the series-shunt machine for which the letters patents now under reduction were granted. In regard to both the pursuers maintain that Mr. Brush is not the first and true inventor, and that both had been publicly known and used prior to the date of the letters patent. To some extent the determination of the question at issue depends upon the construction of Mr. Brush's patent obtained in 1878 and the patent obtained by Mr. Varley in 1876, to some extent also on matters of fact which are disputed. A long proof has been laid before me, from which it was not possible at the time to exclude evidence which ultimately resolved itself into expressions of opinion as to the meaning and construction of the two patents. In forming my judgment upon the questions submitted to me, I have carefully considered the proof, in so far as it was necessary thereby to instruct myself on scientific theory and detail, and in that respect I have obtained great assistance from the evidence adduced on both sides. I would like to add that I have been greatly assisted also by a remarkably able argument from both sides of the Bar. But in construing the letters patent I have put aside the different views of the witnesses on both sides, as construction is a matter for the Court and not for the witnesses.

In disposing of the case, I shall deal separately with the questions connected with the commutators and the series-shunt machine.

Digitized by Google

First. As regards the commutator, Mr. Brush describes his invention in the provisional specification in these terms:—"In constructing commutators cylindrical with an insulating hub or body, to which are attached metallic sub-segments placed in electrical connection with the general mechanism in which the commutator is employed, and metallic wearing sub-segments detachably attached to said sub-segments." This is said to have been anticipated by Varley's commutator and the Manchester commutator, both of which have been produced. With regard to both of the last-mentioned commutators, I think it may be said that they are cylindrical, with metallic sub-segments having metallic wearing segments detachably attached. They also had an "insulating body," or I should rather say "insulating substance," for the word "body" is ambiguous. Yet with all these points of similarity, I do not regard them as anticipations of the defenders' commutator. The insulating hub or body of the defenders' commutator is the "body" or basis on which his commutator is constructed, to which the various parts of his commutator are attached. This cannot be said of the Varley or Manchester commutator, in which the insulating substance does not form the body or basis of the commutator at all, and insulates not the whole commutator, but only one section of it. The purpose and effect of the Varley and Manchester commutators, electrically considered, were in my view the same as Brush's commutator; but it is not in that view that Brush claims that his commutator is a new invention. He claims it merely as a mechanical device or arrangement having certain advantages over existing arrangements used to serve the same purpose. But as a mechanical arrangement I think it was new and useful, and not open to challenge. But the pursuers maintain that the Letters Patent under reduction are rendered invalid by reason of the patentee claiming in his final specification (as amended and disclaimed) something with reference to this commutator as an invention which is not foreshadowed in the provisional specification. The claim here referred to is the fourth, which is in these terms:—"The commutator having metallic insulating segments, T, substantially as shown in division three." It appears to be necessary, or at least desirable and advantageous, to cut the armature bobbins out of circuit when they are crossing the neutral or current-reversing points of the magnetic field. To do this the continuity of the current-conducting segments of the commutator has to be broken, either by a mere space or by the insertion of some non-conducting material at the given point. The cutting of the bobbins out of circuit was known and practised before the date of the defenders' patent, but it was not before then done by means of an insulated metal segment. The advantage which attaches to the defenders' method is this, that the insulated segment being metal, like the conducting segments, there is insured a uniformity of wear over the entire surface of the commutator, which could not be preserved where a softer material like wood was used, or where merely a space was left. I am not aware that prior to the defenders' patent any insulating body, metal or otherwise, was ever used in the construction of the commutator, for the purpose of cutting the bobbins out of circuit. The insulating segment T of the defenders' patent was therefore a novelty, and its utility I do not understand to be disputed. But was it foreshadowed by the provisional specification? I think not.

In the first place, the defenders' second claim seems to me to be co-extensive with the provisional specification (in so far as it relates to the commutator), so that there was nothing left to claim under another head. If all that was foreshadowed in the provisional specification is included in the second claim, then the fourth claim (unless regarded as mere repetition, which nobody suggests) is for something not there foreshadowed. Secondly, the provisional specification relates only to the construction of a cylindrical commutator, whereas one of the chief purposes of and one of the main advantages to be derived from the insulating segment T, is the preservation or maintenance of the cylindricity of the commutator; an object probably as important and as patentable as, but quite distinct from, the shape or mode of construction. Thirdly, the insulating segment T is not merely or necessarily a part of the cylindrical commutator having sub-segments with wearing segments detachably attached. It has and is intended to have a peculiar function which is not referred to in the provisional specification at all. Fourthly, it is said that the segment T is a part of the wearing segment, and therefore falls within the description of the provisional specification; but I think this is not so. The wearing segment is an essential part of the defenders' commutator; the segment T is not—it may be dispensed with altogether.

I come, therefore, on this part of the case, to the conclusion that the patent sought to be reduced is invalid in as much as the invention claimed in the final specification is larger and different from that claimed in the provisional specification.

It is right, notwithstanding what I have said, that I should also express my opinion upon the remaining question in the case, viz., was Mr. Brush the inventor of the series-shunt machine, or had that invention been anticipated by Varley? For the pursuers it is maintained that Varley disclosed and published the invention of a series-shunt machine in his specification and patent of 1876, and constructed a machine in conformity with that specification which was a series-shunt machine and was publicly used as such in 1877. The defenders' patent as I have said is dated in 878

In considering whether the description given by Varley in his specification amounts to a publication of the invention claimed by the defenders, it is necessary to bear in mind the two different kinds of winding used in dynamos known at the time when Varley's specification was lodged. The first of these was the *series*. In the series machine one wire was coiled round the magnets, and the current sent along this wire served both for the excitation of the magnets and the performance of the external work. There was thus one wire and one circuit. In the second—the *shunt* machine—there was again only one wire coiled round the magnets, but the electricity developed by the machine, instead of being entirely conducted in one circuit (as in the series machine), was bifurcated immediately as it left the machine, and one part went wholly to the excitation of the magnets, while the other went wholly to the performance of the external work. The current was thus divided in two, each part of which formed a branch or circuit quite independent of the other. The defects or weak points in each of these machines has been clearly explained by Mr. Imray and need not here be repeated. These defects found their remedy in the third kind of machine now known as *series-shunt*, which, speaking generally, is a compound of the other two; it is in effect a series machine with a shunt added to it. In this machine the magnets are wound round with two insulated wires, one having a higher resistance (the shunt coil) than the other (the series coil). The electricity produced by the machine is diverted, or bifurcated immediately after it leaves the armature; part of it is taken by the shunt to magnetise the magnets, the remainder of it being conducted by the other wire (the series) so as to (1) excite the magnets, and (2) perform the external work. The shunt-circuit is always closed—the other may be either closed or open. Thus, whether the series-circuit is closed and is exciting the magnets, and doing external work, or is open and conveying no energy, the shunt-circuit is engaged in keeping the magnets sufficiently magnetised. For if the series-circuit is open, the only path from the armature being by the shunt, more of the energy produced in the armature will pass through the shunt-circuit, and the effect of the shunt in exciting the magnets will be increased, thus compensating for the absence of any excitation from the series-circuit. The magnetisation of the magnets is in this manner maintained, so that the machine is kept ready to do full work on the series-circuit being again closed.

I turn now to Varley's description, which, for convenience, I here quote. He says, describing his machine, "Part of the electricity developed by the machine is diverted to maintain the magnetism of the soft iron magnets, and the remaining portion is used to produce the electric light. There are several well-known ways of doing this, but the method I prefer is to wrap the soft iron magnets with two insulated wires, one having a larger resistance than the other. The circuit of large resistance is always closed, and the circuit of less resistance is used for the electric light. When the electric light is being produced, the greater portion of electricity passes through the circuit of less resistance, which I term the 'electric light circuit,' maintaining the magnetism of the magnets and producing the light. When the electric light circuit is opened from any cause, the electricity developed passes through the circuit of greater resistance only, and maintains the magnetism of the magnets."

In this description I find disclosed (1)—That the electricity developed by the machine is diverted or divided, one part going to maintain the magnetism of the magnets, and the remainder going to produce the electric light; (2) that the method by which this may be accomplished (and the method which Varley prefers) is by wrapping the magnets with two insulated wires, one having a larger resistance than the other; (3) that the circuit of larger resistance is always closed, and the current passing through it maintains the magnetism of the magnets, and (4) that the current passing through the circuit of lesser resistance is used for "maintaining the magnetism of the magnets and producing the light." These four things appear to me to comprise every distinctive feature of a series-shunt machine. The series arrangement and the shunt arrangement are combined with the compensating or self-regulating result to which I have already alluded.

The defenders' scientific witnesses all express in their examination-in-chief the opinion that Varley did not disclose or publish the series-shunt arrangement in the description which I have already quoted. They find Varley's description to be inconsistent with series-shunt, and suggestive of something quite different. The value of these opinions, however, is seriously diminished when consideration is given to the method by which they are reached. I think I do the defenders' witnesses no injustice when I say that their method is to take Varley's description paragraph by paragraph, each by itself and detached from the context, and then proceed to show how each separate paragraph is, when so read, inconsistent with, or suggestive of something other than series-shunt. As an example of this method of dealing with Varley's description, I may refer to the evidence of Prof. Silvanus Thompson, the first witness examined by the defenders. Such a method is neither reasonable nor fair. To do justice to Varley's description it must be read in its entirety; and when this is done even Prof. Thompson has to admit, as he does on cross-examination, that the description is "consistent with the series-shunt arrangement," which is just a somewhat guarded way of saying that it is descriptive of a series-shunt arrangement. In like manner (but with a greater degree of fairness) Sir William Thomson deals with the description. He finds that there are some things inconsistent with series-shunt—that he "has been puzzled" in trying to understand the description which contains some words of a misleading rather than instructive tendency, and he concludes that an ordinary skilled workman would not in 1876 by Varley's description "have had disclosed to him the system of series-shunt winding." That opinion certainly undergoes modification in the course of his examination, for he concludes his evidence-in-chief (on this part of the case) by saying that he thinks "it quite probable that in 1876 he (the ordinary skilled workman) might have been led to series-shunt by these descriptions." His cross-examination, however, brings him still nearer to the view which I have taken. He says: "The whole passage is consistent with series-shunt winding except the partial inconsistency of the first lines, which is not an absolute inconsistency." On the whole, I think Sir William Thomson may fairly be claimed by the pursuers as a witness in support of their views.

A great deal of evidence is adduced to show that Varley's description would not have enabled an ordinary skilled workman to construct a series-shunt machine, although some of the defenders' witnesses say that from Varley's description it would have been difficult only—not impossible. But assuming the fact to be that from Varley's description alone the ordinary skilled workman could not have constructed a series-shunt machine, that is by no means conclusive of the question in the defenders' favour. A specification may so insufficiently describe the process or the machine

Digitized by Google

patented as to render the patent invalid. It may, nevertheless, contain sufficient description to disclose or publish the invention, so as to prevent its being validly patented by another subsequently; but I think it has been demonstrated that Varley's description was sufficient to enable a workman to make his machine. The model, No. 37, which everyone admits to be a model of a series-shunt wound machine, was made by a lad nineteen years of age, apprenticed to an instrument maker, "from the information derived from Varley's patent with its drawings and from nothing else. It is entirely my own idea of Varley's patent." The same thing was done by others. On the other hand, while there are witnesses brought to say that the description is misleading and inconsistent, no skilled workman has been brought to prove that having tried to make the machine from Varley's description he had been unable to do so.

It is further urged by the defenders that Varley had not, when he invented his machine, any knowledge of the value of series-shunt, and particularly of the quality of "constant potential," which by a series-shunt machine alone of the three I have mentioned can be approximately obtained; that series-shunt was not in his mind, but some method of series-winding with a separate coil for separate excitation; that, on the other hand, Brush knew the value of, and was seeking to find, a self-regulating machine. These matters have not, in my mind, any very direct bearing on the question at issue, but they require to be noticed. In the first place, Varley deposes that in making his specification he "understood the electrical significance of series-shunt winding" and I believe him. It is only due to Mr. Varley that I should say, that whatever may be the soundness or otherwise of his electrical theories, there is no doubt in my mind of his honesty. When he speaks to facts I think he may be entirely relied on. In the second place, whatever value Varley placed on the compound winding of his machine, it was not in his view to make a machine which should proceed on the principle of separate excitation within the machine itself. He made a drawing (No. 40 of process) in November, 1876 (before the date of his provisional specification), which shows that he intended his machine to be a series-shunt, and not a series with separate excitation. With regard to that drawing, Prof. Silvanus Thompson says:—"So far as that drawing goes it indicates a series-shunt arrangement." In the third place, without expressing any opinion as to what may have been the state of knowledge of either Varley or Brush before 1876 or 1878, as to the value of "constant potential," it is certain that neither of them in their respective specifications say anything to indicate their appreciation of the value of the quality, or disclosed any view whatever as to the mode in which it was to be obtained. Even in 1878 constant potential was not felt to be a desideratum in electric machines, and in regard to this matter Varley and Brush for all that appears stand on an equal footing.

Lastly, on this branch of the case, I have to notice that the defenders rely very much upon the fact that Varley in his specification did not claim the invention of compound-winding. But Varley explains why he did not do so, and I have no doubt his explanation is true. Perhaps he was too timid; perhaps he had given a construction and attributed a value to his brother's communication which it would not bear and did not merit. And yet it appears that another skilled electrician at first reading took the same view of that communication which Varley did. But the fact that Varley did not claim a certain invention is no proof that he did not publish it.

I come now to the question whether the defenders' machine was anticipated by user.

A machine was constructed under Varley's specification, in 1876 or 1877, which is produced. I think it is proved to be a series-shunt machine. It has the two coils of wire round the magnets, one of greater resistance than the other, and was capable undoubtedly of being worked as a series-shunt, having an appropriate commutator for that purpose. But some of the defenders' witnesses say it was a merely experimental machine and could be connected in a variety of ways. It was certainly not worked as a series machine with separate excitation, for the commutator used was quite inappropriate to, and negatived the idea of such use. How was it connected? Varley says: "The machine, No. 29, was connected exactly in the way that is represented by that diagram." (No. 40.) Sir William Thomson says that that diagram (*Electrician*, December 7, 1888, p. 140) represents series-shunt. He is asked, "If you were told as a fact that this machine had been connected in accordance with the device shown in that sketch, would that convey to your mind a certainty that this machine had been worked as a series-shunt machine?"—And he answers, "Yes." There are other signs spoken to, which, in the opinion of some of the witnesses, indicate that the machine was worked as a series-shunt; but there are contrary opinions also. I rely upon the evidence of Varley that his machine, which was undoubtedly capable of being connected and worked as a series-shunt, was so connected and worked. He knew best how his machine was connected, and as I have said, on any matter of fact, I have no doubt of Varley's accuracy and truthfulness. Then, if it was so worked, it was worked publicly. It was used publicly to illustrate certain operations in a diving tank and for the purpose of photographing an ice machine. These were not experiments on the machine itself. They were the application of the machine to business purposes, made in the presence of the public, without secrecy or concealment. Very little use of a machine in such circumstances will constitute prior use. "If it is proved distinctly," said Lord Lyndhurst, "that a machine of the same kind was in existence, and was in public use—that is, if use or if trials had been made of it in the eye and in the presence of the public, it is not necessary that it should come down to the time when the patent was granted. If it was discontinued, still that is sufficient evidence of the prior use so as to invalidate the letters patent." Such use of Varley's machine is, I think, distinctly proved. I am of opinion that the defender's machine was anticipated by Varley's, both by publication and use, and that the defender's patent is therefore invalid. I therefore give decree as applied for, with expenses.

Judgment accordingly.

Fyfe v. the Pilsen-Joel and General Electric Light Company (Limited).

This case came before Mr. Justice Mathew, without a jury, last week. It was a claim by the plaintiff for money expended by him as acting member of a committee of investigation, which was appointed last year to inquire into the state of the company, the defence being that such expenditure was unauthorised.

Mr. Kennedy, Q.C., and Mr. T. W. Chitty appeared for the plaintiff: Mr. Scrutton for the defendant.

The plaintiff stated the circumstances under which the committee of investigation, consisting of himself, Mr. Gwynne, Mr. Hopkins, and Mr. Hutton, were appointed, and they were to report to an adjourned meeting in a month. The company had three installations in London in different places, and several miles of wires; the gross income was about £5,000 or £6,000 a year. The committee at the first meeting arranged the programme, to take stock, go through the books, have them written up—and generally ascertain the state of the company's affairs. It would have been utterly impossible for the committee without employing technical assistance to prepare their report within the time named. Mr. Elworthy was employed to take stock, and was paid £50. He gave particulars of the persons employed and also the work they did. One gentleman he had paid £30, though he had only charged £15.

Mr. HUTTON and Mr. HOPKINS gave corroborative evidence, and a deal of correspondence was read. Mr. Hutton said he had not authorised the employment of a valuer and an accountant; he should, no doubt, have done so had he been asked, but he said, when appointed, that he could not give much time to the investigation.

Evidence was also given by some of the gentlemen who did the work in question.

On behalf of the defendants, Mr. W. H. TRENTHAM, formerly secretary to the company, and now one of the voluntary liquidators, was called to state that in February of the present year the stock had been taken, being practically the same as it was in March, 1888, and a charge of 25 guineas only made.

Mr. GWYNNE said he was nominated one of the committee of investigation, but took no part in the proceedings. He was not aware the committee were incurring any expenses. In one of his letters to the plaintiff he referred to the necessity for the stock being valued by an electrician, but he thought the plaintiff would do it himself, or send one of his assistants to do so.

Sir RAWSON W. RAWSON said he was chairman of the company until February of the present year. In the report issued to the shareholders in March, 1888, there was a recommendation that the item of £25,000 appearing in the balance-sheet for goodwill and patent rights should be reduced to £527. In order to ascertain whether that recommendation should be adopted, a stocktaking was not necessary. In his view the intention of the shareholders was that the committee should inquire into the future policy of the company rather than into the past management, but the directors were quite willing that the fullest investigation should be made. The committee were directed to confer with the directors, but no conference was held until either the 5th or 9th of April. If such conference had been held earlier, much of the expenditure could have been saved. When he heard that Mr. Fyfe proposed to have the stock taken, he objected to it as unnecessary. He heard the full details of the expenditure for the first time in court yesterday, except the item of £50 for stocktaking, which he at once stated was preposterous. Up to July 17 plaintiff had made no claim for expenses, but, in prospect of a sale, he then brought in his claim, which the directors objected to. On July 20 the claim was sent in for £100, without any details which the directors asked for, and Mr. Fyfe declined then to give. At the next meeting he produced a Gladstone bag, which he opened, and said it contained the vouchers; the directors declined to examine them, and asked for a detailed statement.

Cross-examined: There was no store clerk and no store ledger. He could not say whether he agreed with Mr. Gwynne that a stocktaking was necessary to a complete report. The details he had given of interviews with plaintiff were not entered in the minutes. He knew in July who had been employed, and he thought that the amount of £100 was preposterous. An injunction was brought by Mr. Fyfe and others to restrain the sale of the company's assets to Mr. Gwynne—a sale to which Mr. Fyfe had previously agreed.

Re-examined: He knew who had been employed, but not what they had been paid.

Mr. SCRUTTON then addressed the Court, and objected that £55. 18s. 6d. of the amount claimed had not been actually paid until after the action was brought.

His LORDSHIP said the writ might be amended by making the claim for "liability incurred," as well as for "money paid.'

Mr. SCRUTTON then argued that there was no liability on the part of the company, and that if there were any liability at all, the proper persons to sue were the committee, and not Mr. Fyfe personally.

Mr. KENNEDY having briefly replied,

His LORDSHIP, in giving judgment, went through the facts of the case, and pointed out that when the claim was first put forward it was not repudiated *in toto* as it had been in court, but particulars were asked for. He held that it must have been intended that the committee should have power to incur any expense necessary in making the investigation, and that it was not unreasonable to employ proper and skilled persons to examine the accounts and take the stock. He could not give effect to any of the technical points raised by the defendants, and he could not say that any of the items charged were unreasonable. He must, therefore give judgment for the plaintiff, with costs.

Judgment accordingly

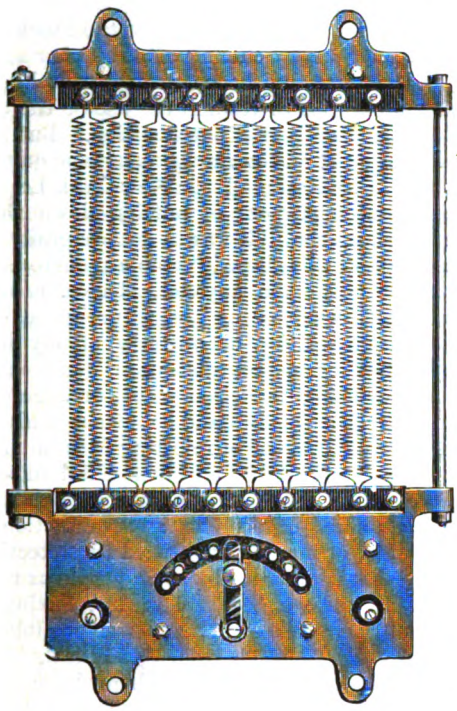
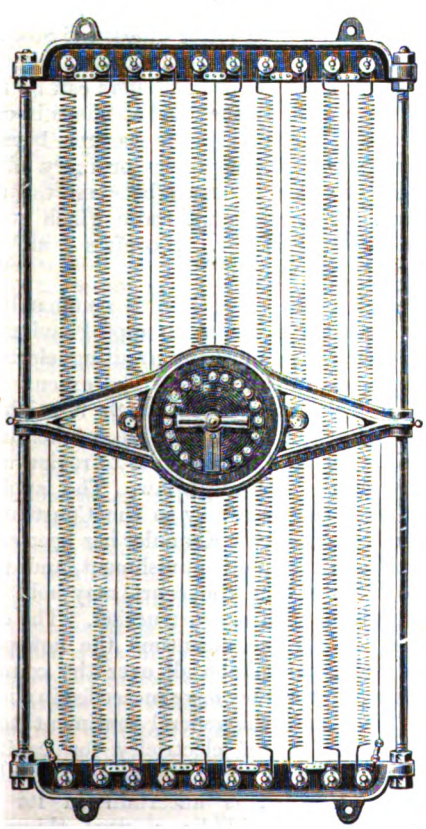
NEW DESIGNS FOR FIRE-PROOF RESISTANCE FRAMES.

The resistance frames illustrated in the adjoining figures have been designed by Messrs. Goolden and Co. to meet the growing



requirements of contractors and central station authorities for means of regulating currents, or for testing purposes. The smaller frame, which is 12in. wide, and of any length up to about 2ft. 6in., according to the resistance required, consists of a cast-iron frame at the



top and bottom, connected by the iron side-rods. These frames are hollow, and have slate slabs fitted in by bolts going right through. The edges of these slabs standing clear of the frame carry the resistance coils, clamped and connected by brass screws and nuts, going right through the slate. A semi-circular opening in the bottom frame allows a series of contact pillars to rise from the slate slab over which the switch passes, cutting in or out resistance.

In the larger pattern the top and bottom frames, made of cast-iron, carry ten wrought-iron pins, cast in the mould, upon which porcelain insulators are secured by split pins; on these insulators the coils are suspended and the ends connected by screwed connectors, from which branch wires are led to the central regulating switch, which is composed of a number of contact pieces mounted on a slate disc, secured by bolts to the cross-frame of iron. This larger pattern is 18in. wide and of varying length up to about 6ft. The coils are made of platinoid, German silver, or tinned or galvanised iron according to the purpose required. The smaller frames may be made for any resistance or current to dissipate up to about 1,000 or 1,200 watts without becoming too hot; the larger frames have been made to dissipate up to about 8,000—10,000 watts. A considerable number of the smaller frames are in use for regulating shunt-wound dynamos or varying the exciting current of alternating dynamos; the larger ones are in use for regulating the charging of sets of accumulators in parallel, regulating motors in transmission of power, &c. These frames satisfy all the requirements of the fire insurance offices, and are very substantially and thoroughly made.

THE WEYMERSCH BATTERY.

The capabilities of the Weymersch battery, as will perhaps be remembered by our readers, were thoroughly tested some twelve months ago by Messrs. Alabaster, Gatehouse and Co., whose report we published at the time (*Electrician*, June 22, 1888, p. 220). These tests showed clearly that M. Weymersch's depolariser was capable of yielding some very good results, one remarkable fact being that the zinc actually consumed was not more than 10 per cent. in excess of the theoretical amount. The Weymersch battery, some details of which we give below, is now being manufactured by the India Rubber, Gutta Percha and Telegraph Works Company of Silvertown.

The standard size consists of a rectangular trough of ebonite, 9½in. by 11in. by 13 75in., divided into six cells by means of ebonite partitions. In each cell is fixed securely a porous pot having a capacity of about one quart, and fitted with a short ebonite pipe. All these pipes are connected to a common pipe, also of ebonite, and provided with an ebonite tap and a gauge glass. It will be seen that by this means all the porous pots are connected together, and can be quickly and easily emptied by merely opening the tap. In a like manner all the outside cells are connected together and fitted with a tap for emptying. The general arrangement has been made with a view to reducing the time required for charging and discharging to a minimum, and permits of either operation being performed in a few minutes without the usual disagreeable labour. Two stoneware barrels, fitted with stoneware taps, are placed on a shelf above the battery level, and connected with the cells by means of suitable lengths of india-rubber tubing One of the barrels is fitted with the exciting liquid, and the other with the new depolariser. When it is required to charge the battery, the india-rubber tubes are fixed upon the mouths of the proper battery taps, and the solutions allowed to flow until they rise to the point indicated on the levels at the end of the battery trough; the battery is now ready for immediate work. When it is required to empty the battery it is only necessary to open the taps and allow the spent solution to flow away. Two zinc plates are placed in each outside cell, one on each side of the porous pot which contains the negative element, carbon and the new depolariser. The carbon heads are well coppered and securely clamped by a tinned brass clamp, into which solder is run, making a perfect and lasting contact, and doing away with the constant trouble usually given by carbon contacts. The carbons and zincs are carried on a wooden slab which has been well boiled in paraffin wax, and which forms the battery lid; the connecting strips are of stout brass well tinned. The zincs are sent out by the makers specially amalgamated, and if the current is not allowed to exceed the maximum for which the battery is designed, they will not require re-amalgamating, the first amalgamation lasting as long as the zincs.

The E.M.F. of the standard battery on open circuit, the dimensions of which have already been given, is 13 volts for the six cells. It is designed to give a current of 15 amperes for about seven hours continuously. The total charge of depolarising solution for the six cells is 11 pints, and the total energy given out is about 1,300 watt-hours, of which between 750 and 800 watt-hours are expended in the external circuit, or say 230 watt-hours per quart of solution. The current remains nearly constant during the first seven hours after charging, rising slowly for the first two hours, and after remaining constant for three or four hours, slowly falling for the rest of the time, so that at the end of the run the current is about the

Digitized by Google

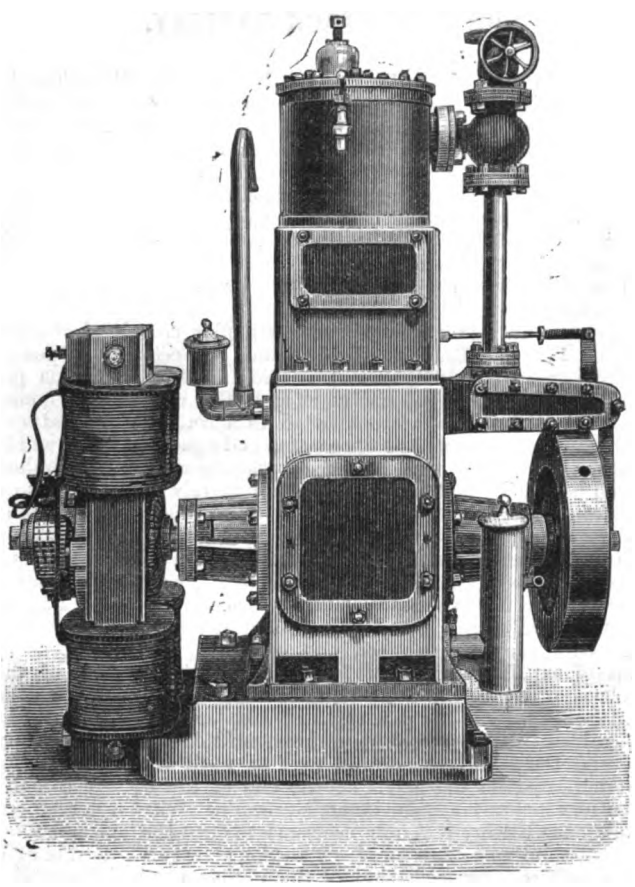
same as at starting. This rise and fall, however, is very small. If after the first seven hours' work the current be reduced to 10 amperes, a further constant run giving about 400 watt-hours may be obtained, thus giving a total energy per quart of depolariser of about 305 watt-hours. Two of the standard size batteries will run 10 8 candle-power or 16 5 candle-power incandescent lamps for seven hours, and, as indicated above, if the number of lamps is reduced at the end of this time, a further run of three or four hours can be obtained.

For transport the depolariser is supplied in the form of salts, which require the addition of water only in order to obtain the solution. The exciting liquid is a solution of sulphuric acid and water in the proportion of 1 of acid to 18 of water.

This battery, it will be thus seen, is very suitable for small installations where facilities exist for handling acids or for light motor work in situations where it would be inconvenient to use power derived from a dynamo machine.

THE CHANDLER HIGH-SPEED ENGINE.

Since their first introduction a few years back, the Chandler "silent" high-speed engines have proved themselves specially



The Chandler High-Speed Engine and Crompton Dynamo.

suited for use on board ship, where their compactness, reliability, and absence of noise renders them invaluable. The excellent results which have been obtained with these single-acting engines are doubtless due as much as anything to high-class workmanship and the very perfect method of lubrication adopted. Crank-shafts, connecting rods, &c., are all of steel, and the bearings, which are of great length and diameter, are of phosphor-bronze, and work in a bath of oil.

The above block shows one of these engines combined with a Crompton dynamo. This arrangement, as will be seen, is of a very compact description. No outside bearing is required for the dynamo, as the armature is close up to the bearing of the engine, and the crank shaft being exceptionally strong, and a long bearing being used, the armature simply acts as a small flywheel. The dynamo runs at 600 revolutions, and is capable of supplying fifty 16 candle-power lamps.

These engines, for which there is at the present moment a very large demand, are made by Mr. F. D. Bumsted, of Hednesford.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 15, 1889.

There are further interesting developments this week with regard to the ticker trouble about which I wrote you extensively in my last letter. The movement of the Stock Exchange against the bucket shops by cutting off the ticker service was soon seen to be a failure, and hence there was nothing for the Stock Exchange to do but to resume the use of the tickers, as it very sensibly did after a brief intermission. But the stock-brokers now find support and encouragement from quite another quarter. At the last meeting of the New York Legislature a Bill was passed for the purpose of putting down the bucket shops. The object of the Bill was to declare guilty of a misdemeanour any person who should "keep a room to be used for making wagers or bets upon any lot, chance, casualty, unknown or contingent event, or on the future price of stocks, bonds, securities, commodities, or property of any description whatever, or for making any contract for or on account of any money, property or thing in action so bet or wagered." The Governor has now reached this Bill, and has attached his signature to it, rendering it valid, instead of rejecting it as he might have done. He says that he thinks it is an honest Bill and one which should therefore become law. He is convinced, he says, that it will not injuriously affect or prohibit any transaction or business which rightfully or morally is entitled to protection, while it will put down what is regarded by some people as respectable gambling. This is quite a heavy blow, but having survived the deprivation of their ticker service, it is possible that the bucket shops may live through even this ordeal. They are running in full blast, and some of them have issued an announcement to their customers to the effect that their business will not be affected by the Bill in any way, and that they will receive and execute orders "with the same understanding hereafter as before, actual deliveries being in all cases contemplated and understood." In some quarters it is said that Governor Hill would not have signed this Bill if he did not believe that it is practically to be inoperative. The fact is that it will probably remain a dead letter unless the Stock Exchange itself makes a business of seeing to its enforcement, and then, perhaps, some good may come of it. There can be no question as to the great harm done by the bucket shops in encouraging gambling and dishonesty amongst messenger boys and poor young clerks, but it very often puzzles ordinary folk to understand just where the line is drawn between the ethics that apply to bucket-shop practice and those which govern transactions on the Stock Exchange. I confess I am not casuist enough to draw the line myself.

The matter of electrical executions is commanding a large share of public attention just now, an appeal having been made on behalf of Kemmler, the murderer awaiting electrical execution at Auburn prison in this State. The execution has been postponed, and it begins to look as though it might not take place after all. Further steps have been taken bringing the matter before the General Term in order to review and test the constitutionality of the electrical law. The application for *habeas corpus* alleges that, contrary to the Constitution of the State and of the United States, Kemmler has been sentenced to undergo a "cruel and unusual" punishment, and there seems good reason to believe that the court may hold the use of electricity to be within such a construction. The case will be argued on June 18. In the meantime the newspapers have been canvassing electrical opinion all over the country, and it must be said that as far as they have succeeded in eliciting views on the subject they show the general sentiment to run very strongly against the use of electricity for capital punishment. Dr. Vander Weyde offers the suggestion that instead of using electricity, which is uncertain in its results on the human system, it would be a good thing to substitute suffocation by illuminating gas, which is well known to be perfectly successful in killing people. Back of the general feeling against the use of electricity at all is another feeling that the opportunity has been seized for business

Digitized by Google

and commercial reasons to bring the alternating current into disrepute and to attach suspicion to the Westinghouse system. So far has the discussion on this particular point gone, that one of the leading lawyers, in taking up the case for Kemmler, seizes the occasion to state that he is not retained by the Westinghouse Company. The general feeling among electricians is that if it were actually wanted to kill the criminal outright it would be easy enough to do it by taking an arc current of 3,000 or 4,000 volts and applying it direct, whereas it is proposed instead to use the alternating current down to as low a voltage as may be possible and thus show that the alternating current is not a safe thing to use for general purposes. Of course, the use of a current of higher electro-motive force would be likely to result in horrible mutilation of the body, and in other disagreeable features, but even then there would be considerable uncertainty in any given case. Altogether it may be said that American electricians are not a little tired and disgusted over the matter, especially as two or three other States are proposing to follow New York's example in the matter. Massachusetts, for example, is just falling into line, and a Bill is now before the Senate Judiciary Committee there, allowing the death sentence to be carried out by electrical means.

The New York Legislature has authorised the expenditure of $3,000,000 for the repairing and paving of the streets of this city, and a great many people are asking what will be the good of spending all this money when the streets will be ripped up again almost as soon as they are put down? The condition of the New York streets, in fact, tends from bad to worse, not because the money is not forthcoming to keep them in order, nor because the work is badly done, but for the reason that the stones are no sooner down than they are up again. If the road paving is not disturbed by the Gas Company, the Steam-Heating Company is likely to supply the omission, and if both these parties fail the Subway people are sure to come along and turn things topsy-turvy. If all these should fail, something is found to be the matter with the water pipes. Thus it happens that from the beginning of the year to the end, and even when frost renders the ground as hard as a rock, some of the streets are broken up, and present the appearance of barricaded French thoroughfares, with piles of earth and stone breast high. Some idea of the extent to which the streets are ripped up may be formed from the fact that during the last six months of 1888 the Steam-Heating Company alone made 240 excavations for purposes of repair and 28 for service connections. This alone would be enough to ruin the finest paving in the world. Now that there is talk of an extension of the subway system, and that $3,000,000 is to be spent on repairing the paving and streets, there is also a very general feeling that the subways ought to be built before the work begins, or else that it would be better to get along without them. This situation with regard to the subways gives an interest at this time to the bids which the electric light companies are making for the city lighting. The local companies have decided to make a difference in their bids for districts where there are subways and those where there are not. They propose to charge 65 cents where subways exist, and 35 cents elsewhere, and they have tendered at this rate. The Gas Commission, however, has rejected the bids of the six companies, and now bids will be advertised for with the idea, it is said, of breaking up the "combine" which the companies have made. Major Grant is understood to be very much put out because the Grand Jury has declined to indict the electric light companies for assumed violations of his edict, and perhaps, as he is a member of the Gas Commission, this is one of his ways of getting even. Everybody knows that it is considerably more costly for the companies to supply light through wires in the conduits than it is by means of overhead wires, and it is only to be expected that they would have different rates for the different class of work.

Some interesting trials have been made this week of the improved Sims-Edison torpedo at Willet's Point, near this city. The torpedo in question was approved and adopted by the Government some time ago, but certain improvements were deemed necessary, and it would appear that they have now been introduced. This torpedo is governed and operated from *terra firma*, or a ship if desired. It carries a small motor, and is connected with the shore by means of a very light conductor, through which current travels from a dynamo. By means of this current the vessel is not only propelled but steered in any desired direction. In the tests which have been made this week, the torpedo used was 31ft. long and 28in. in diameter, weighing 3,000 pounds. The speed attained was at the rate of about 21 miles an hour in a run of over 800ft., current being supplied at the rate, it is said, of 25 amperes and 900 volts, the 30in. screw making about 900 revolutions per minute. This torpedo, the electrical attachments for which have been studied out by Mr. Edison and built at the Edison machine works, is very easily manipulated and manœuvred, and can not only be steered at any angle, but can be made to dive under any obstruction met when running. In view of the fact that we have so few men-of-war, and yet have so large a coast to defend, it is thought extremely probable that the torpedo service will have to be one of our chief arms of marine warfare.

There is every prospect that the electrical welding business based on the process invented and elaborated by Prof. Elihu Thomson will develop into quite a large department of industry. The Thomson Electric Welding Company, although they have but just begun business, are already enlarging their factory at Lynn, having work on hand for several months to come. They have recently been given an order from the Trenton Iron Company for machines to weld steel wire-cable. The tests on welded specimens of this cable which were made at one of the United States arsenals show an efficiency of 82 per cent. of the tensile strength of the original cable. Another application for the apparatus that I heard of this week is its use in a new barrel factory at Worcester, Mass., where the hoops for the barrels are made out of steel wire welded. It is said that this method is at once economical and effective.

Telegraphic history in this country includes the careers of a great many men who have risen from the ranks and become leaders in the service; in fact, there are very few men at the head of telegraphic affairs here who have not begun life as telegraph messenger-boys or as operators. These numerous instances of promotion are a good exemplification of the fact that in this country Napoleon's aphorism, that a career is always open to talent, is better justified than under any of the conditions which prevail in the Old World. But for examples of telegraph messengers and operators who have risen in the world we need not look to the ranks of telegraphy alone; we may find them in almost every branch of the electrical profession. A great many of them, again, on leaving the telegraphic field have attained distinction in a variety of occupations, and some of them are to-day among the best-known men in the country. In this last class I may mention such a notability as Andrew Carnegie, who got his first overcoat while a poor little messenger-boy in Pittsburgh, and who to-day by his well-considered and frequent benefactions on the largest scale is setting a splendid example to other rich men of the wise employment of wealth. Mr. Carnegie's rise in the world is recalled by the fact that another Pittsburgh telegraph boy has made his mark. Last week President Harrison appointed Mr Arthur L. Thomas to be Governor of the territory of Utah. Only as recently as 1869 young Thomas was engaged in Pittsburgh in distributing the press reports to each paper. At that time he was wont to amuse the operators in the lunch hour by telling them of his ambition to follow Horace Greeley's advice by going West and growing up with the country, so that he might come back to Washington as a Congressman. Just about that time a local politician was elected to Congress after a hard fight, in which he received the support of the Welsh element. Desiring to return the favour in some degree, he asked his Welsh constituents to pick out somebody that he might secure a position for at Washington. The choice fell upon the messenger boy, and he was given a clerical appointment in the House of Representatives. There his intelligence and willingness made him many friends among the senators and representatives, and he remained in the office until he was made Secretary for Utah by President Garfield. He then became a member of the Election Commission of the territory, and now becomes its Governor. Thus at the age of 34 he reaches one of the highest positions of the

Digitized by Google

country, with a prospect of the attainment of even greater honours.

As you were always among those who regarded the speculative development of the electric sugar-refining process with suspicion, and were foremost in predicting the ultimate exposure of the fraud, you will be interested to know that the disclosures which were made a month or two ago when the stock of the concern went down to zero have been followed up by even more absurd and startling revelations in the case which has been brought by the State against the late Prof. Friend's confederates. It will be remembered that Prof. Friend was willing to have submitted to him the worst possible trash in the shape of raw sugar for manipulation, and that no matter how bad its condition, after it had gone through his secret treatment, it came out as good as could be obtained in the market. The purity of the sugar was certainly wonderful, but it need no longer be marvelled at, because this week witnesses have been on the stand who have proved the sale to the defendant of "quantities of mould A" sugar, the purest refined made by Havemeyer and Elder. Another interesting little fact is that the dates of the sales coincide with the dates of the various extraordinary "runs" of electric sugar, and the quantities are almost identical with those turned out to the bewilderment of the investors in the stock. Other witnesses have been on the stand who testified to smashing the refined sugar with hammers, while others gave evidence as to getting it ready for the famous "runs" from the roof to the cellar. After this I do not think anybody will be likely to express any more faith in this big swindle. The joke of the whole matter is that the well-meant advice of electricians to the fools who were determined to put their money into the swindle was treated with the utmost scorn and contempt, and that Prof. Friend was outspoken in his hostility to electric experts. He would have none of them. In this respect, however, he was not singular. I heard of a case the other day in which a bright young electrical engineer sought to obtain employment from one of the newest storage battery companies. Thinking to recommend himself by a statement of how much he knew and could do, he naturally began to enumerate his qualifications and to enlarge on his experience. Much to his surprise, however, the gentleman who calls himself the electrician of the company told him that he did not want to have any such man about him. What he wanted was men who did not know anything. When I add that the person who made this remark is responsible for building storage batteries of a shape that long since became obsolete, it will readily be understood that he is capable of just such an utterance. The only pity is that a man of such calibre should enjoy the confidence of capitalists and be entrusted with the electrical work of what might be a large concern. The young fellow that I speak of was of course greatly annoyed and chagrined by the incident, and now is somewhat in doubt as to what capacity he shall appear in when he next applies for a position.

CORRESPONDENCE.

RECENT GAS BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your last issue of the 21st you mention a gas battery devised by Mr. Ludwig Mond and Dr. Carl Langer, and which evidently is much the same as some made and described by me in the *English Mechanic*, Nos. 1,245, 1,246, 1,249, 1,252, 1,253, 1,255, 1,257, in this year's issue, and as I lay claim to being the first to use either pierced or wire-mesh plates covered with platinum black, and the method of passing air over or through the plate in order to evaporate the surplus water and to generate ozone in the plate, I should feel much obliged if you would publish this, for this method has been known and practised by me for the last two years, as my letters to the *English Mechanic* will show.

The discussion on gas batteries in the above paper, from No. 1,243 to No. 1,257, might prove interesting to some of your readers. Also I must say I consider, with all due deference to the constructors of the battery mentioned by you, that the result obtained is a very poor return from a plate-area of 120 inches square, for, as far as I can understand from your report, its action merely depends on the occlusion of gas in the plate itself, the supply of gas being intermittent, whereas the action of a gas battery ought to depend not on the inherent property of a certain metal or substance to occlude gas, but on the intermolecular porosity of the plate itself—granted that intermolecular action is that property which allows of the passing of a gas or liquid through any substance which gas or liquid is condensed in or among the particles of the substance in passing through, and remains inert in that condition until called for, *i.e.*, on the closing of the circuit; and this property, as I have explained in the above-mentioned letters, is increased by the subdivision of the substance itself, and the less the intermolecular porosity the greater the pressure of gas required, the greater the intermolecular porosity the less pressure required, except so far as to overcome the capillary attraction of the acid to the plate; if this capillary attraction is destroyed, the gas will pass through the plate at any point above the pressure of acid it is required to sustain—that is, height of cell.

Apologising for the length of this letter, which I cannot help asking you to publish in justice to myself—Yours, &c,

ALFRED TREEBY.

BOROUGH OF BRADFORD: PROPOSED BYE-LAWS IN CONNECTION WITH THE CORPORATION SUPPLY OF ELECTRICITY.

The Board of Trade, in pursuance of the power vested in them in that behalf, hereby make and ordain the following bye-laws for the better ensuring safety in the supply of electricity by the Mayor, Aldermen and burgesses of the said borough, hereafter called the Corporation, pursuant to the provisions of the Electric Lighting Act, 1882, and the Act of 46 and 47 Vic., cap. 220, confirming the Bradford Provisional Order for such supply of electricity; that is to say:—

Rules for wiring of Houses. 1. All wiring, fittings, apparatus, and other appliances, must be supplied and fixed in accordance with the "Rules and Regulations of the Society of Telegraph Engineers and Electricians" (April, 1888), and of any other regulations which the Corporation may require.

Conductors. 2. The sectional area of all conductors shall be so proportioned that the maximum current conveyed in any conductor shall not exceed the ratio of 1,000 amperes per square inch of section of copper conductor.

No portion of the metal work of any brackets, electroliers, or other electrical fittings, or of any gas or water pipe, is to be used as part of the electrical metallic circuit as "earths" might readily be formed by any such connections.

Insulation Resistance of Installation. 3. The insulation resistance of the entire installation (when all the mains, wires, fittings, lamps, motors, and other appliances are fixed) shall not, as proved to the satisfaction of the Corporation, be less than the total number of ohms which shall be indicated by the number resulting from the division of 10,000,000 by the number expressing the maximum electric current in amperes which has been named by the consumer in his application for his supply of electricity.

In the event of the insulation at any time falling below the above standard, and continuing so, the Corporation may, after due notice, discontinue the supply of electricity to the premises.

Unauthorised Extensions. Penalty attached to. 4. Should it be found that any consumer is using a current in excess of the maximum with which he has required the Undertakers to supply him, without notice having been given in accordance with the Act, the Corporation may, if they think fit, discontinue the electric supply to this consumer until they have made proper provision for such increase.

"Earths." 5. All connections direct with "earth," or connections tending to cause "earth," such as with gas or water pipes or other metallic bodies are absolutely forbidden, without the express sanction in writing of the Corporation.

Penalty attached thereto. 6. Should any such "earths" be at any time found to exist in an installation, whether through an intentionally made connection or by neglect of any of the prescribed regulations as to wiring or as to fittings, or from any other cause, the Corporation, if they deem it necessary or advisable, may discontinue, even without notice, the supply of electricity to the installation until such "earths" or other defect has been made good by the consumer to the entire satisfaction of the Corporation, and so notified in writing.

Digitized by Google

Dead ends, &c., to be sealed up. 7. All dead ends which may occur in the installation should have their extremities carefully sealed up, so as to avoid all chance of "earths" being formed therefrom.

Notice as to leaks. 8. Should any leak, or "earth," or other serious defect be discovered by the consumer, either within the installation itself, or in its immediate vicinity outside the premises, he is bound at once and without delay to give notice thereof to the Corporation or their Electrical Engineer, so that the defect may be at once properly remedied.

Main disconnecting switches. 9. Two switches, one on each main respectively shall be fixed, in a readily accessible position, on the two mains leading from the meter to the premises, at a point immediately adjacent to the meter, if possible, and subject to the approval of the Corporation or their Electrical Engineer. These switches must be so arranged that the entire of the current passing into the installation can be, when necessary, cut off by them.

Access to main switches by Corporation officials. 10. The proper officers of the Corporation shall have the right of access at all times to these switches.

Alterations, repairs, &c., notice of. 11. In the event of any alterations, repairs, extensions, or other interference, from whatever cause, with the ordinary working of the installation, notice must be given to the Corporation or their Electrical Engineer at least twenty-four hours before such alterations or other operations commence, and indicating the time at which it is intended to commence such operations.

Current to be cut-off during alterations, repairs, &c. 12. During the entire time, whether continuously or with interruptions, that such alterations or other operations are in course of execution, the electric supply from the outside must be entirely disconnected from the premises by means of both of the above-named main disconnecting switches. Any exception to this regulation must have the express sanction in writing of the Corporation or their Electrical Engineer.

Interruptions by Corporation during alterations, repairs, &c. 13. In the event of the electric supply not being properly and efficiently cut off from the premises whilst such alterations, repairs, or other operations are being carried on, the officers of the Corporation may, if they deem it necessary, even without notice, completely interrupt the electric supply to the premises, in any way which they think advisable.

Disturbance of streets, &c., in vicinity of electrical cables, &c. 14. Whenever any disturbance or other interference may be required or contemplated, with the surface or other parts of any street, causeway, pavement, or any other place in the vicinity of any electrical cables, wires, or other apparatus or matter connected with the public supply of electricity, the person or body charged with carrying out the above-named disturbance, or interference with such street, or other places, shall give notice in writing of such intention to the Corporation.

15. Such notice should, where possible, be delivered at least twenty-four hours before the commencement of such intended disturbance or other interference.

Notice to the Electrical Engineer's office. 16. The notice should also designate the locality of such intended disturbance, &c., as also the time at which such operations are proposed to be commenced, so as to allow of the attendance at such locality of an official from the Electrical Engineer, in order to point out the exact position of the electrical cables, wires, and other apparatus, and also that he may take any steps required for the proper protection thereof.

Penalty. 17. Any person offending against or not complying with any of the above regulations shall be liable to a penalty not exceeding £5, and a daily recurring penalty not exceeding such sum so long as the offence or neglect may continue.

Electrical Engineer. 18. In the above bye-laws, the term Electrical Engineer shall mean the person whom the Corporation may from time to time appoint to take charge of their electrical works.

Office. 19. The Corporation shall appoint an office in the Town Hall, where all notices may be served in connection with the above bye-laws.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

June 8, 1889.

9,537. J. A. Timmis. London. Improvements in incandescent electric lamps.

9,541. F. Lindley. London. Improvements in appliances for attaching telegraph and other wires to insulators and similar uses.

9,571. J. E. Kingsbury. London. Arrangement of circuits and apparatus to be used in connection with telephonic communication (F. R. Welles, Belgium).

9,576. H. H. Lake. London. Improvements in and relating to incandescent electric lamps (S. F. Van Choate, United States).

June 11, 1889.

9,589. J. C. Ricketson. London. Improvements in electric signals for indicating the direction and speed of revolution of engine shaft

9,638. E. S. Drake. London. Improvements in telephonic and phonographic transmitters.

9,659. A. H. Norman. London. Improvements in and connected with electric batteries.

June 12, 1889.

9,667. G. Wilkinson. London. Improvements in apparatus for the generation of electricity.

9,681. R. Tatham. Liverpool. Improvements in electrical storage or secondary batteries.

9,713. J. G. Lorrain. Strand. Improvements in electric conductors (La Société d'Exploitation des Cables Electriques Système Berthoud, Borel et Cie., Switzerland).

9,723. The Electrical Power Storage Company and P. J. Rea. London. Improvements in grids or containers for the elements or plates of secondary batteries and moulds to be used in their manufacture.

SPECIFICATIONS PUBLISHED.

1888.

8,525. Rawson and John. Electric trembling bells. (Price 8d.)

10,092. Lineff. Supplying electricity to tramcars, &c. (Price 11d.)

10,299. Wallace (Scott). Electric logs. (Price 8d.)

10,654. Mortimer and Holloway. Electric arc lamps. (Price 8d.)

10,929. Cox-Walker and Swinton. Magneto-electric generators, &c. (Price 8d.)

THE SCOTTISH ELECTRIC SUPPLY COMPANY (LIMITED).

We have received the prospectus of this Company, which has a capital of £100,000, in 10,000 shares of £10 each, with power to increase. The present issue is 2,500 shares of £10 each.

The following constitute the influential Board of Directors :—

G. F. Armstrong, C.E., Regius Professor of Engineering in the University of Edinburgh.

W. Allan Carter, M Inst.C.E., 5, St. Andrew-square, Edinburgh.

John Henry Davidson, Merchant, 133, Princes-street, Edinburgh.

Wm. Geipel, M.Inst.E.E., and Lecturer on Electrical Engineering in the Heriot-Watt College, 19, Great King-street, Edinburgh.

Alex. Low, of Laws, Advocate, 12, Drumsheugh-gardens, Edinburgh.

Charles Ritchie, S.S.C., 20, Hill-street, Edinburgh.

Lieut.-Colonel G. Mure Steel, 4, Atholl-crescent, Edinburgh.

The consulting engineer is Mr. Alan A. Campbell Swinton, Assoc.Inst.E.E., of 66, Victoria-street, London, S.W.; the secretaries are Messrs. Brewis and Rainie, C.A., and the offices are situate at 5, North St. David-street, Edinburgh.

In the prospectus the directors state that they believe the work of electric lighting and the supply of electric power in Edinburgh and surrounding district (combined, if necessary, with the other business referred to in the Memorandum of Association) can be established on a sound and scientific basis and at a profit to shareholders. They have carefully considered reports furnished by experts, and estimates of cost, and have made arrangements for ground suitable for a central station at Lochrin, adjoining the Union Canal, where there is ample room for extension, and where coal can be obtained at the lowest cost. When expedient the directors intend to apply for a Provisional Order under the Electric Lighting Act of 1888. No promotion-money has been or will be paid.

[The Lists of Application will close on or before to-morrow (Saturday).]

COMPANIES' MEETINGS & REPORTS.

South of England Telephone Company (Limited).

The sixth ordinary general meeting of the shareholders of this Company was held yesterday at Winchester House, Old Broad-street, Mr. D. Owen Bateson presiding.

The SECRETARY (Mr. Fred. L. Robinson) having read the notice calling the meeting,

The CHAIRMAN said: Since our last annual meeting we have lost one of our number. Mr. Campbell was one of our original Directors, and while his health lasted was most regular in his attendance at our Board meetings. His services were much valued by us, as he brought to our consultations an amount of good sense and great business aptitude, which we highly appreciated. His departure from among us was, I assure you, deeply deplored. Mr. Charles Billete was elected to the vacant chair, and from our experience of his services since his election I am quite convinced we have made no mistake in his appointment. The figures we have laid before you in our balance-sheet show the progress of the Company during the past financial year; they are sufficiently full, so they require very little explanation on my part. It will be noted that our expenditure on capital account is £19,917. 12s. 6d.; this exceeds last year by £3,460. 5s. 9d., which is accounted for by the increase of business in a great measure, viz., 451 exchange and 114 private lines, and I think ought to be satisfactory to the shareholders, as it results in a substantial increase in our gross rentals. Another matter tending towards increased expenditure has been the rise in the value of copper wire; this, however, is now over, at all events for the present, and we are obtaining our supplies of this article at

Digitized by Google

much more moderate prices than have been current during the past twelve months. Again, we have spent a good deal of money on trunk lines in our district, joining up the several towns in which we have exchanges, and gradually connecting them together, so that when the good time comes which we have been so long expecting when we shall be admitted into London, only short lengths will be required to enable us to join hands to the Metropolitan system. The revenue, £18,792. 15s. 3d., shows an increase of rentals over last year of £4,928. 5s. 4d., but we are obliged to transfer £9,041. 8s. 11d., which is an increase of £2,070. 12s. 11d., to the present year; the great activity in our business being in the summer, the unearned increment consequently is proportionately large. This sum, however, will be for disposal during the year we have just entered on. You will note the large sum we have paid for royalties, £3,455. 3s. 7d. This is a very heavy tax on our resources, really amounting to 7 per cent. on our paid-up capital. With respect to this item of royalties, I notice in a very able letter from the United Company to the Secretary of the Post Office, they "suggest that the public would be better served if the heavy tax imposed by the Post Office upon telephonic communication were removed." Upon this I would venture to suggest that it would be an additional service to the public were the large royalties levied by the United Company on the subsidiary companies abolished, or at least materially modified. Were this done it might strengthen the hands of the United Company in any negotiation with the Post Office, and be certainly a good example for the department to follow. I am glad to say that since we last met we have obtained from the Stock Exchange a quotation on the market; this, I take it, will be of considerable service to us, as it makes our shares a much more marketable security than formerly. Both Ordinary and Preference shares are now quoted. You will note from the report that the long standing dispute with the United Company has been settled, and the invidious memorandum inserted by the auditors in our former balance-sheets, had been eliminated this year. We succeeded in reducing the claim from £1,845 to £1,264. This I think is sufficient justification for your directors in resisting what they considered an unfair demand. The whole of the payment has been carried to the debit of revenue with the exception of £148. 16s. 8d., the unexpired rent of the Brighton trunk wire, and of course goes to the reduction of our net profits this year. The year's proportion of preliminary expenses, £373. 19s. 7d., has been charged to revenue. The balance of this account will entirely disappear in our next balance-sheet. I am sorry to say that we have made no progress towards connecting our district with the Metropolitan system. The demand for trunk lines for this purpose from our subscribers continues, but as yet the United Company have not seen fit to grant any facilities in this direction, though we have constantly urged the matter on their attention. I understand they are running lines through our district, as under our agreement they have undoubtedly the power, with the intention of connecting up Birmingham in one direction and Bristol in another, but why they are willing to grant accommodation to these distant towns, and refuse it to places contiguous to their own centre, and to parties, many of whom are already subscribers to the London Exchange, is a matter I cannot understand. The lines I allude to pass through our district, and we have reason to complain that they are being run without any consultation with us as to the route they should take, so as to interfere as little as possible with our way-leave arrangements, which year by year are becoming more difficult to manage, and we think it would have been a matter of only ordinary courtesy had our views been asked before the lines were decided on. I really think that a little more regard might have been paid to the convenience of a Company to which they have assigned a district and in whose success they have so large an interest both as regards royalties and dividends. I hope the new management, as I expect there will be new management, will put such matters as this on a better footing in future. There is another thing I wish to allude to before I finish and that is our relations with the Post Office. I notice there has been a good deal said and some hard words used with reference to the treatment experienced by other companies from this department of the public service. I can only say as regards the South of England Company, that they have always received the greatest courtesy at the hands of the department. We know very well the terms upon which we hold the license, and though its terms are onerous enough, we have never tried to go behind or beyond its requirements. We have in no instance asked anything that has not been granted by them, and on our part as the terms of the license are sufficiently clear we can easily calculate the approximate amount of our royalties, and having done this a cheque for the amount is forwarded without delay. I named this matter in justice to a public office from which we have always received the utmost consideration, and with which we have always worked without the slightest friction. The dividend we propose to pay on the Ordinary shares of the Company (the distribution of 6 per cent. per annum on the Preferences having already been made, and they amount to nearly £1,000 more than last year), is 1 per cent. This is ½ per cent. more than last year, and I hope it will be approved of by the shareholders. The balance, £627. 1s. 2d., we intend to carry forward to this year. There is nothing more that I need say on the subject, but I should be very glad to answer any questions that may be asked. I beg to propose

"*That the report and accounts for the year ended 30th April, 1889, now presented be adopted and passed.*"

Mr. ALEXANDER MACGREGOR seconded the motion, which was unanimously adopted.

The CHAIRMAN next moved:—

"*That a dividend at the rate of 1 per cent., free of income-tax, on the Ordinary Shares be now declared, payable on the 28th June.*"

Mr. CHARLES BILLETT seconded the resolution, which was carried.

Mr. DELF asked whether Northampton was to be connected with London, and whether there was any chance of the Company being amalgamated with the United Company. He thought that by amalgamating both Companies would be strengthened.

The CHAIRMAN: I quite agree that unity is strength, but up to the present the matter lies entirely in the hands of the United Company, and we have not yet been approached upon the subject, therefore we do not know what is passing. You know quite as much as the Directors do. As regards the Northampton line the United Company are proposing to run a line between London and Birmingham, but so far as I know nothing has been done with the line from Northampton to London.

On the motion of the CHAIRMAN, seconded by Mr. ROBERTS, the retiring Director, Mr. Alexander MacGregor, was re-elected to his seat at the Board.

On the motion of Mr. PONSFORD, seconded by Mr. ROBERTS, the following resolution was unanimously agreed to:—

"*That the sum of £200 be paid to the Directors for their services during the year ended 30th April, 1889.*"

Mr. BISHOP proposed and Mr. ROBERTS seconded—

"*That Mr. John Weise, of Messrs. Turquand, Youngs and Co., be re-elected Auditor for the present year, with a remuneration of 40 guineas.*"

The proceedings then terminated.

Manchester Edison-Swan Company (Limited).

The annual meeting of the shareholders of this Company was held on Tuesday last at the Memorial Hall, Manchester, Mr. Vernon K. Armitage in the chair.

The following report of the Directors, for the year ending 31st May, which had previously been circulated amongst the shareholders, was taken as read:—

The Directors beg to submit the accompanying balance-sheet. The net profit, including last year's balance, amounts to £2,754. 11s. 7d., which it is proposed to appropriate as follows:—To payment of dividend at 5 per cent. per annum, £1,000; to reserve fund, £1,000; balance, £754. 11s. 7d.—total,

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.
PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.
SOLE PROPRIETORS of the British, Indian and Colonial Patents,
THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

£2,754. 11s. 7d. If the above be approved the dividend warrants will be issued on the 5th July, 1889. During the past year there has been a considerable increase in the business done by the Company, not only in the United Kingdom, but also abroad. The satisfactory working of the numerous electric lighting plants installed, and the growing demand for both arc and incandescent lighting afford great encouragement for the future. The negotiations with the Manchester Corporation for the establishment of a central station in the city have been continued, but as yet without any definite result. The Company have given the Corporation formal notice of their intention to apply to the Board of Trade for a Provisional Order, and in the meantime have asked their assent to an application for a License. Hitherto the Directors have refrained from asking any remuneration for their services, but they consider the time has now arrived when this matter may properly be dealt with. In accordance with the Company's articles of association, the Chairman, Mr. Vernon Kirk Armitage, retires from the Board. He is, however, eligible, and offers himself for re-election.

The CHAIRMAN said that he thought they would agree with him that they had reason to congratulate themselves on the result of the year's work. Their confidence that prosperity would come some day or another to the Company was now in process of being justified. He attributed a very large share of the prosperity the Company was enjoying and seemed about to enjoy to the very excellent work of their managing director, Mr. Williamson. As showing the increased demand for the light which was referred to in the report, he might say that they had installed nearly 7,000 lamps in the course of the year, and that they had sent out estimates for some 30,000—a considerably larger percentage of installations in proportion to estimates sent out than they had in former years. The most satisfactory item in the balance-sheet was that whereas last year there was only some £1,700 of profit to dispose of, this year they had £2,700. He might further say that since the 31st of May of this year they had obtained orders to the amount of nearly £5,000. With regard to the negotiations with the Manchester Corporation, it would be remembered that at the extraordinary general meeting of the Company held recently the Directors informed the shareholders that the Manchester Corporation seemed to be holding their hands and waiting for some evidence of the wish of the public for the establishment of electric lighting stations in Manchester, and the first thing that was done, after the shareholders' consent had been given to the resolution proposed at that meeting, was to issue a circular enclosing a postcard asking the recipients to state if they would be willing to take the electric light in case it were installed in the centre of Manchester. The Directors only contemplated the establishment of a central station for 10,000 lights, but they obtained in the course of three or four weeks postcards filled up by people who were prepared to take something like 14,500 lights. With that information in their hands they approached the Manchester Corporation again, and he must say he was disappointed that no further advance had been made. It was true the Corporation had appointed a committee to deal with the whole question, but what that committee had done, or whether it had done anything, he was not in a position to say. As it might be eighteen months before the Company got the Provisional Order for which they had applied, and of which application they had given notice to the Corporation, they had asked the Corporation to assent to an application they had made for a Provisional License, by obtaining which they would be able to set to work within a much shorter time than eighteen months. They had only received in reply an intimation that the committee would take the matter into consideration. How long the consideration of the matter would take, or whether it would throw them back another year with their application to the Board of Trade he did not know. All he could say was that they would do their best to urge on the Corporation the importance of their ceasing to occupy a merely obstructive position in connection with so important a subject as electric lighting. With regard to the shares of the Company, he was glad to say that they had recovered from the position in which they were placed by the foolish action of one of the shareholders at the last meeting, and unless there were more foolish shareholders who were prepared to sacrifice their property, he did not believe they were likely to have a recurrence of such a state of things as that which followed the last meeting. He moved that the report be approved and adopted.

Sir J. C. LEE seconded the motion, which was carried.

Mr. GRIMSHAW asked whether the Directors had any definite information as to the intentions of the Corporation?

The CHAIRMAN: None whatever.

Mr. GRIMSHAW said he had been told by an alderman that the Corporation intended to apply for a license themselves, and to take the whole thing in their own hands.

The CHAIRMAN said there could be no doubt that the Corporation did prepare a Provisional Order some six or eight years ago, but it had never got out of the municipal offices. The Corporation, of course, could not use the Edison-Swan Company's patents. Whatever they did they would have to go to somebody, and whoever did the work the Edison-Swan Company would no doubt come in for a considerable share of it.

The CHAIRMAN moved, and Mr. EDWARD CROSS seconded, a motion in favour of the division of the profits, as recommended in the report, but this motion was afterwards withdrawn in favour of one by Mr. CHARLES AGNEW, seconded by Mr. RICHARD WHEELDON, to the effect that the profits be divided as recommended, except that the sum of £300 be divided amongst the Directors for their services during the year. Mr. Agnew spoke in high praise of the Directors' services to the Company.

The motion was adopted.

On the motion of Mr. AGNEW, seconded by Mr. J. F. FISHER, Mr. V. K. Armitage was re-elected a Director of the Company.

Major S. FLOOD PAGE, one of the Directors of the Company, gave details of the patent actions in which the parent Company in London have been involved, and which have now ended successfully for the Company. He spoke hopefully of the position and prospects of the Manchester Edison-Swan Company.

A vote of thanks to the Directors brought the meeting to a close.

NEW COMPANIES REGISTERED.

CROMPTON ELECTRIC SUPPLY COMPANY OF AUSTRALIA (LIMITED). This company was registered on the 18th inst., with a capital of £50,000, in £5 shares, to carry on in the Australasian Colonies the business of contractors for the supply of electricity. The number of directors is not to be less than three, nor more than four; qualification, £200 in shares; the first are Viscount Torrington, J. F. Albright, of Chelmsford, and W. G. Whiffen, of Lombard-road, Battersea. Messrs. Harrison and Whiffen are appointed managers.

WOLVERHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This company was registered on the 18th inst., with a capital of £50,000 in £10 shares, to establish at Wolverhampton, or within a radius of 10 miles thereof, works for the production, storage, transmission, and use of light, heat, electric, magnetic or other force. There are 23 signatories for one share each, all of whom are resident in Wolverhampton and neighbourhood. The number of directors is not to be less than three nor more than eight, the first being Messrs. Alfred Hickman, Charles Wells, C. T. Mander, J. Ayre Sparrow, E. Pritchard, and T. J. Barnett; qualification, 50 shares or £500 stock: remuneration, £300 per annum and 10 per cent. on all divisible profits after payment of 7 per cent. dividend.

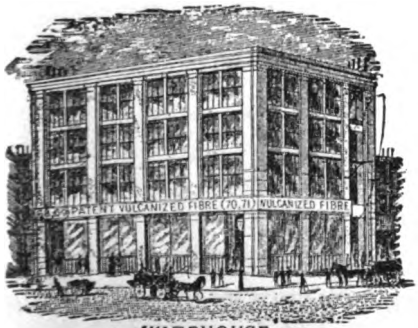
CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 14, 1889, amounted to £3,205, and for the week ended June 21, to £2,414.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 14, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,099, and for the week ended June 21, £1,567.

EDISON-SWAN LAMPS.—The Edison-Swan Company send us a notice of alteration in prices of their incandescent lamp. The alteration takes place as from the 1st July. It is further announced that a new and complete lamp list is in preparation. A copy of the notice can be obtained from the office of the company, at 100, Victoria-street, S.W.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

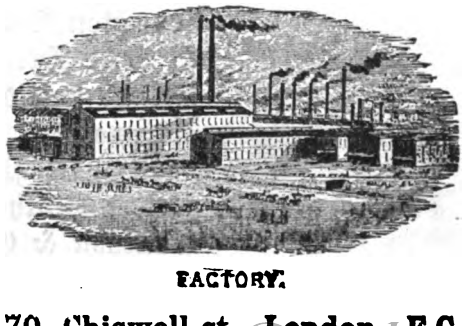
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50th. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Johnson & Phillips.
Nalder Brothers & Co.
Paterson & Cooper.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 581.—Vol. XXIII. FRIDAY, JULY 5, 1889. Price Fourpence.

NOTES.

Although, as we learn, Lord Trayner's decision is to be appealed to the Inner House, the inducement to continue the struggle can be but small, seeing that the patent soon dies a natural death. Meanwhile the position of the large number of firms who have submitted to the payment of royalties is, at first sight, somewhat ludicrous. They may, however, take to themselves the consolation of believing that had the question been fought out in the English Courts the costs would unquestionably have far exceeded the total value of the royalties paid; and, moreover, without the least disrespect for the impartiality or the integrity of the judicial bench, we may add that it by no means follows that the decision arrived at would necessarily have been the same. We say this, not merely in view of the proverbial "glorious uncertainty" of the law, but especially with relation to the very singular circumstances of the case. Laying aside the altogether unimportant issue of the "cylindrical commutator with wearing segments detachably attached," in respect of which the Court would surely have permitted a disclaimer had the Brush patent been held otherwise valid, we come to this broad fact: Varley had not—at the date in question he could not possibly have had—the least idea of the use and purport of compound winding as applied in modern dynamos. What we understand of compound winding is something very different from a mere chance combination of shunt and series coils. That Varley was altogether oblivious of the possibilities involved in the modern applications of the device was frankly admitted by his counsel, who however imputed the same degree of ignorance to Brush at the date of *his* patent. On behalf of the latter, this aspersion has been vigorously denied; and although upon the crucial point of the attainment of constancy of potential his specification might well be more explicit, yet it is clear enough that he knew a good deal more about it than did Varley. In the light of these facts it must be difficult for anyone to feel any especial enthusiasm on behalf of either claimant. They each stumbled across an idea which happened to be capable of development into a remarkably useful device. One of them was certainly not looking for anything of the kind; the other was probably groping his way towards it, and at the very least must be credited with clearer views than any of his immediate contemporaries. To us it seems difficult to believe that the judicial mind must necessarily and inevitably take only one view of the question at issue—though we have not the least desire to insinuate that Lord Trayner's decision does not meet the justice of the case as well as any other.

At the very moment when the industry had hopes of the surcease of a burden, which, though by no means heavy, was no doubt somewhat vexatious, a far weightier and more onerous charge (if we are correctly informed) is sought to be laid upon it. Dynamos are not all compound-wound, but they have for the most part iron in their armatures, and the iron is invariably laminated. Our readers are already aware that in the United States a claim for the exclusive use of such armatures has been set up on behalf of an early patent of Edward Weston, and this claim has lately been recognised by the Edison Company. Here, however, the tables, it would seem, are to be turned, and Edison is the patentee whose rights in this country are now to be insisted on. On April 5th, 1880, a patent, No. 1385, was filed on behalf of Edison under the title of "Improvements in dynamo or magneto-electric machines and electric motors." This was one of Edison's somewhat unhappy "omnibus" patents, and included no less than ten claims, many of which are nowadays easily seen to be worthless, whilst others it would be difficult to construe as relating to one and the same invention. However, on July 12th, 1882, the Commissioners consented to the filing of a disclaimer by which all but a single claim was discarded. This claim reads as follows:—

"A rotating armature, composed of thin metal plates, discs, or rings as described, with alternating interposed insulating material secured together upon a shaft or hub, substantially as set forth."

This patent is now the property of Messrs. Mather and Platt, and why it has been allowed to rest in obscurity all these years, or why it is brought upon the scene at this particular juncture, we are at a loss to imagine. This firm also holds a patent (No. 15,648) of 1884, upon which we understand they are inclined to lay stress. Their specification, which was filed by Mr. W. Mather and Drs. John and Edward Hopkinson, describes several features which are common to modern dynamos, though whether the improvements are sufficiently definite in character to form a valid patent is possibly an open question.

The recent discussion on the influence of self-induction upon the working of alternators in parallel or as synchronous motors renders the publication by Professor Ayrton of the actual value of the self-induction coefficient in the case of several such machines singularly opportune. We trust that either Prof. Ayrton himself or others interested will add

Digitized by Google

considerably to the number of such measurements. The introduction of the direct-reading variable standard of self-induction has much simplified the process, and although the secohmmeter is, no doubt, a rather expensive piece of apparatus, it ought to be regarded as indispensable for all workers in alternating currents. In reprinting this Paper, owing to the demands upon our space we have been obliged to omit the mathematical part of the section "On the Effect of Self-Induction in destroying Ripples," but the nature of the results arrived at will easily be understood from the abstract.

BUT perhaps the greatest interest attaches to the simple and ingenious device which Prof. AYRTON calls the Electric Frequency Meter, and which we have lately had the pleasure of examining at the Laboratory in the Exhibition-road. It is unfortunate that the difficulty of providing a suitable alternating current precluded an exhibition of these experiments before the Institution of Electrical Engineers. Had this been possible we are sure that much interest and enthusiasm would have been aroused. At the time of our visit, although the apparatus had not been carried beyond the earliest experimental stage, the results were attained with great ease, and it was extremely curious to hear the wire conveying the current break into loud sonorous vibration as soon as its free length had been adjusted to suit the period of alternation. The overtones corresponding to "ripples" on the current-wave were only faintly heard, but by a suitable choice of diameter, material, and stretching force applied to the wire, there can be little doubt that an appliance of great scientific interest, and perhaps also of some practical value, may easily be perfected.

WE may also mention that for some time past several of Prof. AYRTON'S students have been engaged (under his direction) in a very extensive and elaborate investigation upon the efficiency and output of secondary batteries. Already some results of a curious and unexpected character have been arrived at. It was very soon discovered that what is sometimes called the "ampere-hour efficiency" might in a single experiment be almost anything you please, and might easily exceed 100 per cent. *according to the previous history of the cells.* It is therefore necessary before drawing any conclusion that the battery should be regularly charged and discharged with precisely the same number of coulombs for a sufficiently long period to bring it as nearly as possible into a perfectly normal condition. For this purpose and for subsequent accurate measurements a system of automatic control of the charge and discharge has been devised, which, although decidedly complex in appearance, does its work in a most effective manner. We look eventually for a Paper of great interest—one which will probably throw light on some of the most obscure phenomena of the secondary battery—as the outcome of these experiments.

THE able and suggestive article on "Problems in Electric Traction," by Dr. LOUIS BELL, which we reprint this week from the *Electrical World*, will doubtless be read with interest by those who are connected with electric traction in this country. Dr. BELL, we are glad to see, re-echoes our oft-repeated opinion that an ideal solution of the many difficulties besetting electric traction would be furnished by batteries, "if the storage battery comes to be of reasonable durability and weight." With respect to the very low commercial efficiency (25 per cent.) of the Lafayette line, Dr. BELL puts the saddle on the right horse when he remarks that the key to the whole situation lies in the immensely irregular calls for power, and suggests as the best remedy the employment of engines specially built to meet the exigencies of tramway work, the problem being "to work an engine on the average at its most economical point of cut-off, while retaining the power to respond to sudden, though brief, demands for several times the average horse-power." The article is full of good points, for which we must refer our readers to our reprint, or to the excellent summary in our American correspondence.

THERE would seem to be good reason to believe that the puzzling phenomenon of the dark flash has at last received a satisfactory explanation. Mr. A. W. CLAYDEN, at the last meeting of the Physical Society, exhibited some photographs, copies of which will be found elsewhere in this issue, showing both "natural" and artificial dark flashes. After all it seems to be merely a photographic effect due to the presence of white clouds in the background. The author referred at the meeting to one difficulty which seemed to require explanation, viz., the crossing of a dark flash by a bright one, but he has since informed us that he has succeeded without difficulty in reproducing the phenomenon, the point of crossing appearing to be extra bright, just as in the case of the photographs of lightning.

WE are indebted to the editor of *L'Elettricità* for some interesting information respecting the recent discovery of an important manuscript of GALVANI'S, to which we referred in our issue of the 31st May. A manuscript belonging to GALVANI has, it seems, been actually found in the Communal Library at Bologna, though it is not the manuscript of an unknown treatise by the great *savant*, the work to which it belongs being "De viribus Electricitatis in motu musculari," which was published about the year 1792. The discovery is, however, of considerable historic interest on account of the large number of marginal notes in GALVANI'S own handwriting which this treasure-trove contains.

IT will be noted that in the last letter of the Board of Trade to the London County Council the duties of Electrical Inspectors as regards meters are spoken of as if they were confined merely to certifying them "to be of some construction and pattern, and to have been fixed and to have been connected with the service lines in some manner approved of by the Board of Trade." This would be satisfactory so far as it goes; but, as we pointed out last week, the Model Order further prescribes that the Inspector shall certify every meter "to be a correct meter."

MR. EDISON, we are glad to learn, has definitely promised by telegram to visit the Electrical Exhibition at Birmingham in August, and steps are being taken to give him a fitting reception. The opening of the Exhibition is fixed for the 1st August.

Digitized by Google

Wakefield.—A London company will apply to Parliament in the next session for powers to light this town by electricity for public and private purposes.

Personal.—We learn that Mr. R. J. Browne, who was assistant electrician at Glasgow International Exhibition, has left this country to fill an important position in India.

An English Westinghouse Company.—We understand that an English branch of the Westinghouse Company is being organised, and will probably come out in the course of a few days.

A Correction.—In the description of the Elmore Process in *The Electrician*, June 14th, the current density should be 15 amperes per square foot of cathode, not "square inch" as stated.

Dublin.—On Saturday last the solicitor for the Irish House-to-House Electricity Company served a notice on the Corporation, announcing the intention of that Company to apply for a Provisional Order.

West African Telegraph Company.—The numbers of the Five per Cent. Mortgage Debentures of this Company, which will be paid off on the 2nd September next, will be found in our advertisement columns.

Bradford.—The municipal electric light station at Bradford is so nearly complete that a trial of the engines and dynamos is to be made in a day or two. In a month or six weeks, it is expected, light will be supplied to customers.

The Society of Arts Conversazione.—The Conversazione given by the Society of Arts at South Kensington last Friday was of a very brilliant description. The guests, who were received by the Duke of Abercorn, C.B., numbered upwards of two thousand.

Segovia (Spain).—The streets of Segovia will shortly be lighted by two 300 candle-power, ten 50 candle-power, and two hundred 16 candle-power incandescent lamps. The motive power for the dynamos is obtained from a waterfall, about a mile from the town.

Plymouth.—A company called the Devon and Cornwall Electricity Supply Company has been formed at Plymouth for the purpose of establishing a central station from which electricity can be supplied over a large radius, including Devonport, Stonehouse, and the suburbs.

Royal Institution.—At the general monthly meeting of the Royal Institution on Monday last Messrs. Robert Kaye Gray, James Mactear, William James Russell, and James Miln Small were elected members. Sir James Crichton-Browne, M.D., F.R.S., was elected treasurer of the Royal Institution.

Barmen.—We are informed by Herr Paul Bürsche, who was responsible for the accumulator arrangements of the Barmen central station, about which we gave a few particulars in our last issue, that the dynamos are only worked as a rule four hours per diem, in lieu of 10 hours, as stated in the note in question.

Frankfort-on-the-Main.—In Frankfort-on-the Main the long-debated question whether the town should undertake the private electric light supply, or leave it to a company, has been settled in favour of the supply being undertaken by the town. It is expected that the works will be in going order by the 1st of October.

Horfield Local Board.—At the last meeting of this Board letters were read from the Electric Lighting Maintenance Company (Limited), London, and the Western House-to-House Electric Lighting Company (Limited), stating their intention to apply to the Board of Trade for a Provisional Order to introduce electric lighting into the district.

Important Sale of Plant and Machinery.—We would draw the attention of our readers to the fact that this day (Friday) is the concluding day of the important sale by Messrs. Wheatley Kirk, Price and Goulty, at the Suffolk Works, Berkley-street, Birmingham, of the plant, machinery, stock, stores, and utensils announced in our advertisement columns last week.

Whipple's Electrical Publications.—Messrs. Woodhouse and Rawson, of 11, Queen Victoria-street, E.C., have taken up the agency for Mr. Whipple's publications, several of which are well known in this country. They include his book on "Municipal Lighting," the second annual number of which has just appeared, the "Electric Railway," and his "National Electrical Directory."

Chatham.—At a meeting of the Chatham Local Board of Health on Friday last a letter was received from the Chatham and Rochester Electric Lighting Company, asking the Board to consent to an application for a Provisional Order by the Company. It was resolved, after considerable discussion, that the Board must have a copy of the proposed Order before considering the matter further.

"The Steamship."—A new monthly journal, called *The Steamship*, appeared on the first of the month. *The Steamship* is to be a scientific journal devoted to the interests of marine engineers, shipbuilders and shipowners. Amongst the articles contained in the first number we notice one on "Electric Lighting," by G. J. Burns, B.Sc., and an illustrated description of the Cox-Walker-Swinton Magneto-electric Signal Bells for ships.

Underground Electric Light Cables.—Up to the present time, says the Berlin correspondent of *Industries*, the joints between the lead cables which are used in connection with the Berlin central electric light stations were made by special clamps, it having been considered impracticable to make soldered joints between heavy cables; but now one of the engineers of the company has invented a method of soldering even the heaviest cables, whereby injury to the insulating material is avoided, the application of heat being purely local.

An Advantage of the Telephone.—The advantage of the use of the telephone in assisting the police to discover or to prevent crime was recently strikingly exemplified in Dundee. A servant noticed a man climbing over the wall of an empty house close by. She immediately apprised her mistress of the circumstance. The house being connected by telephone, the lady promptly called up the Central Police Office, the result being that within a few minutes the residence was surrounded by a cordon of police and the would-be burglar was soon captured.

St. Margaret's and St. John's Vestry.—At a meeting of this Vestry, on Wednesday, last week, the Parliamentary Committee reported upon the recent inquiry held by Major Marindin, and recommended "that the Vestry reserve its consideration of the schemes for the lighting of the parishes by electricity and the proposed Provisional Orders until the Bill relating thereto has been introduced into Parliament, and that the Board of Trade be informed accordingly; and that the Committee be authorised, in case of necessity, to petition against the Bills affecting the parish." The recommendation was agreed to.

Electric Light Experiments at the Entrance of the Solent.—Some electric light experiments which were carried out at the beginning of last week at the Needles resulted in favour of the light. Six gunboats and six torpedo boats left Portland with the intention of forcing a passage at the entrance of the Solent, hoping by raising thick volumes of smoke to conceal their presence. But, steaming head to wind, the smoke was carried astern, and each vessel was distinctly seen several miles off, and, with the aid of powerful glasses, the numbers of the torpedo boats were read as soon as the vessels came within range of quick-firing guns.

Postal Telegraph Revenue.—The Revenue returns for the quarter ended 30th June show an unusually large augmentation of the gross receipts from the Telegraph Service. Compared with the June quarter last year there has been an increase of £45,000; and on a comparison of the annual periods ending June 1888 and June 1889, the increase during the latter amounts to £160,000. Details for the four quarters of the two years are as follows:—

	Sep. 30.	Dec. 31.	Mar. 31.	June 30.	Total.
1888-9	£565,000...	£515,000...	£520,000...	£525,000...	£2,125,000
1887-8	540,000...	465,000...	480,000...	480,000...	1,965,000
Increase ...	£25,000	£50,000	£40,000	£45,000	£160,000

Proposed Telpher Line between Brechin and Edzell.—A meeting of gentlemen interested in the construction of a telpher line between Brechin and Edzell was recently held at Brechin. Mr. Manville, of the United Electrical Engineering Company, explained the construction and working of the system, and

Digitized by Google

stated that he estimated the cost of the proposed line, which will be about six miles in length, at about £16,000. The speed would be about twelve miles an hour for a train of five carriages, each holding five passengers, and the trains would be despatched in quick succession—say, one every half-hour. Those present at the meeting expressed themselves very favourably disposed to the project, and the landowners on the route seemed willing to give way-leaves for the erection of the posts. It was agreed to provide funds for preliminary expenses.

The French Government and the Telephones.—It will be seen by the following resolution, which was passed unanimously at the last meeting of the shareholders of the Société Générale des Téléphones, that the proposals of the French Government (*The Electrician*, June 21, p. 160) are likely to meet with a determined opposition in this quarter:—"The shareholders of the Société Générale des Téléphones, after having heard the explications given by their Board with regard to the purchase scheme proposed in the Chamber of Deputies, consider that these proposals constitute a breach of previous agreements, and amount to a veritable confiscation. They, therefore, protest against the scheme, approve of the conduct of the Board in the past, and rely on their firmness in the future." It should be mentioned that proceedings have already been taken against the State to enforce the carrying out of the convention of July 22, 1886.

Proposed Dinner of the Institution of Electrical Engineers.—The following circular has been issued to the members of the Institute, and it is to be hoped that it will meet with such a response as to justify an annual fixture:—

Dear Sir,—I am instructed by the Council to inform you that it is proposed that the Institution should hold a dinner, on the 4th of November next, to which a certain number of distinguished guests would be invited. In order to enable the Council to form some approximate estimate as to the provision to be made as regards numbers, it is desirable that they should ascertain as soon as possible what members are likely to attend, and I have to request therefore the favour of your informing me whether you will be disposed to do so providing you find your engagements will so permit. The price of the dinner tickets will not exceed 10s. 6d. exclusive of wine. Should the Council find that the feeling of the members generally is in favour of the dinner being made an annual institution, they will make arrangements accordingly.—I am, dear sir, faithfully yours, F. H. Webb, Secretary.

Electrical Conferences at the Paris Exhibition.—The Société Internationale des Electriciens has organised a series of "conferences-visites," which will take place every Tuesday and Thursday. These conferences will commence at 10 a.m. at places previously announced:—

July 4.—M. Napoli: Apparatus of Precision.
,, 9.—M. Sarcia: Accumulators.
,, 11.—M. Seligmann-Lui: Telegraphy.
,, 18.—M. Hospitalier: Commercial Measuring Instruments.
,, 23.—M. le Capitaine de Place: Military Electrical Apparatus.
,, 25.—M. Dumont: Railway Apparatus.
,, 30.—M. Hillairet: Motors and Transmission of Power.
Aug. 1.—M. de la Touane: Telephony.
,, 6.—M. Arnoux: Continuous-current Dynamos.
,, 8.—M. Lemonnier: The Applications of the Electric Light in the Army and Navy.
,, 13.—M. Picou: Alternators and Transformers.

Portsmouth.—On Thursday evening last week, at the invitation of the South Hants Electric Supply Company, a meeting was held at the Esplanade Hotel, Southsea, for the purpose of listening to a short address by Mr. Bate, representing the Laing, Wharton and Down Construction Syndicate, on the Thomson-Houston system of electric lighting, which has just been temporarily installed at that hotel. Mr. Bate, after explaining the Thomson-Houston system, said that the Corporation had refused to give the South Hants Company permission to run overhead wires temporarily, pending the obtaining of the Provisional Order for which they had applied. He could not help feeling that it had been refused under a misapprehension that they sought a permanent permission. They had already over 100 orders in different parts of the town, but they could not proceed to execute them until their Provisional Order was out. In the course of a discussion which followed, it was mentioned that the Roads and Works Committee had received an application from another company for their consent to a Provisional Order.

Wimbledon.—At the last meeting of the Wimbledon Local Board, the members had under consideration a proposal by the South Western District and Thames Valley Electricity Supply Company (Limited) to supply electricity to a large district, embracing Wandsworth, Wimbledon, New Malden, Surbiton, Kingston, Ham, Richmond, Mortlake, Barnes, Kew, and Putney. The company was registered on Friday last with a capital of £100,000 and power to increase. Contracts will, after the Provisional Orders have been obtained, be entered into with responsible firms to lay underground mains throughout the district, capable of supplying 100,000 lamps from three centres at Kingston, Mortlake, and Wandsworth respectively, and to supply generating plant for 50,000 lamps at once. The contractors will also work the stations and supply the current required, the charge per Board of Trade unit being 4½d. The projectors claim that they enter upon the work under the most favourable conditions. The Chairman of the Board remarked that it was one thing for the Company to show their sanguine figures on paper, and another to realise them after a few years' experience. The Company's communication was referred to the Electric Lighting Committee. It is stated that the Board are also applying for a license to enable them to light the district under their jurisdiction by means of electricity.

Electro-motive Force of Amalgams.—Experiments on the E.M.F. of amalgams immersed in an electrolyte such as zinc sulphate or dilute sulphuric acid have been made by Crova, in Germany; Gaugain, in France; and Hockin and Taylor in England. It was found that excessively small traces of zinc or cadmium made a marked difference in the E.M.F. of mercury. Thus an amalgam investigated by Hockin and Taylor, consisting of 1 part zinc to 23·6 million parts of mercury in sulphate of zinc, was discovered to be more positive than pure mercury by 0·01 volt, and an amalgam composed of 1 part cadmium in 5·7 million parts of mercury was shown to be more positive than pure mercury by 0·09 volt. A German scientist, Herr S. Lindeck, in a recent Paper, contributed *Ann. Phys. Chem.* [2], 35, 311-331, describes a series of experiments that he has made on amalgams of zinc, cadmium, silver, lead, and tin. The results of this investigation are graphically exhibited by means of curves, in which the percentage of the metal alloyed with the mercury is plotted against the corresponding change in the difference of potential. Hockin and Taylor's results are confirmed, and by comparing these curves Lindeck infers the following conclusions:—1. The higher the position of a metal in the electromotive series, the higher will the addition of a slight trace of it raise the position of mercury in the series. 2. A further addition of metal produces scarcely any effect; the amalgam containing a mere trace of the metal occupies practically the same position in the series as a bar of amalgamated metal. 3. In whatever proportions silver and mercury be amalgamated, the amalgam occupies approximately the same position in the series as that occupied by pure mercury.

Lambeth Vestry.—At a meeting of this Vestry last week the Clerk made a lengthy statement upon the subject of the London and Metropolitan Electric Lighting Orders. The result of the long inquiry which took place before Major Marindin was that the London Company were allowed an Order for that part of Lambeth north of Westminster-bridge-road, while the Metropolitan Company were allowed the whole of the parish. Before the Board of Trade considerable discussion took place on the question of the Metropolitan Company laying wires in various parts of the parish, and their representative eventually agreed to lay them down on the Albert-embankment, South Lambeth-road, Kennington-road, Kennington-park-road, Clapham-road to the Swan, and Brixton-road to the church, in addition to some half-dozen important roads in the north of the parish. He was, therefore, much surprised on receiving a letter from the Company stating that, beyond the streets in the northern parts and the Clapham-road, they could schedule none, because they were the only ones in which in the immediate future there was any likelihood of there being any demand for electric lighting. Under those circumstances he (the Clerk)

Digitized by Google

felt justified in advising the Vestry to strongly oppose the Order, unless the Company did justice to the southern parts of the parish. The Electric Lighting Committee presented a report in accordance with the Clerk's statement, and the report was adopted.

Leeds.—On Wednesday last Mr. Lee Hardwick moved that the Council authorise the lighting by electricity of such portions of the Town Hall and Municipal Buildings mentioned in the report of the Electric Lighting Committee (the substance of which we published in our last issue), at an estimated expenditure of £3,000.—The resolution was unanimously adopted.—Mr. Lee Hardwick next moved that the Council apply to the Board of Trade for a Provisional Order authorising the Corporation to supply electricity for public and private purposes within the area referred to in the Report, at an estimated total capital expenditure of £68,000.—Mr. Battle moved an amendment to the effect that it was not desirable for the Corporation to supply electricity for public or private lighting purposes, as in the opinion of the Council such supply could be advantageously provided by private enterprise. They were asked, he said, to embark in an enterprise of a most speculative character, and there was not a single member of the Committee who supported it that would invest his own money in it if it were to be carried out by the Electric Lighting Committee. He could not understand intelligent business men undertaking such a scheme for a moment.—After considerable discussion the amendment was lost, whereupon Mr. Kettlewell moved another, to the effect that the question be referred back to the Committee to report further, especially as to the annual cost of the present installation, and as to the cost in other towns where the electric light had been adopted.—This having been seconded, was adopted.

Electric Energy and Light.—Under this head Mr. J. W. Moore, of Lafayette College, Easton, U.S., writes as follows to our esteemed contemporary, the New York *Electrical Engineer*:—

Apropos of the recent experiments of Prof. Stone on electrical energy and light, I send you some struggles after the relations between these two physical conditions. They were unsuccessful—that is, the results were negative—but sometimes I imagined that I did observe a slight change in the intensity of sound in the telephone. They will illustrate some of the gropings after the truth which are now going on. I copy from my laboratory note book for 1884:—

Experiment 1 was a repetition of Faraday's experiment of the rotation of the plane of polarisation of light by magnetism.

Experiment 2.—The analyser was removed; a piece of unannealed glass was wound with fine insulated wire; the wire was connected with a Bell receiver. The glass having been placed in front of the polariser the latter was made to rotate rapidly on its axis. No sound was heard in the telephone.

Experiment 3.—The polariser was fixed; the glass and telephone were allowed to remain as in experiment 2. A cardboard disc, perforated with a series of holes arranged in a circle, attached to a rotator, was made to rotate with various velocities in the path of the light entering the polariser. The light was thus divided into a great number of paths. No sound was heard in the telephone.

Experiment 4.—The siren was removed, everything else remaining the same. The glass was subjected to pressure with a screw. When it was alternately compressed and released from pressure no sound was heard in the telephone.

Experiment 5 was the same as 4, except that the glass was permanently compressed and suddenly passed through the beam of light.

Experiment 6.—The preceding experiments were all repeated with two telephones in circuit, opposite one of which a tuning-fork was placed. No change was noticed in the intensity of sound.

Experiment 7.—A Hughes' sonometer was introduced in a microphone circuit. The glass and other bodies surrounded by their coils were placed singly in the microphone circuit. The telephone failed to show any change in the ticking of the watch on the microphone stand when all the previous experiments were repeated.

Experiment 8.—A Hughes' induction balance was placed in circuit. All the previous experiments were reproduced with similar results.

Many variations were made in the length and diameter of the wire. The material was changed. Pressure was applied transversely and longitudinally. A soft iron core was also placed in the coil of wire. When the microphone was placed in circuit, it was found necessary to remove the watch and substitute an electric vibro-scope. The battery was also changed to get rid of variations in strength of current. The "frying" noise of the microphone was obviated by changing the form of the instrument, so that a smooth sound of constant intensity was heard.

The Birmingham Exhibition.—The following is a list of the chief electrical firms who will take part in the forthcoming Electrical and Industrial Exhibition at Bingley Hall, most of whom will send working exhibits:—Acme Electric Works—electric light and telegraphic apparatus; Admiralty—Whitehead torpedos (whole and section), submarine electric mines, electric exploders, batteries, keys, switches, Wheatstone bridges, lamps and other electric apparatus for torpedo service; Anglo-American Brush Electric Light Corporation (Limited)—engines, Brush dynamos, arc lamps, incandescent lamps, Mordey dynamos, transformers, &c.; Appleton, Berbey and Williams—switches, batteries, electric light fittings, &c.; Avery, W. and T.—Snelgrove electric weighing machine, weighing for general purposes and bullion, chemical and other sensitive balances, Snelgrove's patent electric beds, &c.; Buller, Jobson and Co.—telegraph poles, fittings for telephonic and electric light purposes, articles in porcelain; Callender Bitumen Telegraphic and Waterproof Company (Limited)—electric light mains and underground systems as used in London, Liverpool, on the Continent and United States; Canning, W., and Co.—dynamos, vats, solutions, chemicals, and all things required for electro-depositing; Coad, T.—batteries, lamps, &c.; Corporation of Birmingham (per Mr. Prime)—the first dynamo constructed for depositing metal; Crompton and Co.—electric lighting, electric crane, &c.; Crossley and Co., gas engines, dynamos, lighting, &c.; Cruickshank, R.—dynamos, machines for electro-depositing, regulators, switch-boards, &c; Davis, J., and Son—electric light fittings, &c.; Eclipse Electrical Case Works—cases for electrical telephone batteries, &c.; Edison and Swan United Electric Light Company (Limited)—electric incandescent lamps and fittings, electric miners' lamp, &c.; Electrical Power Storage Company (Limited)—accumulators for central lighting, &c., automatic switch batteries, &c.;—Elwell-Parker (Limited)—dynamos, batteries, motors, &c.; J. Fowler and Co.—samples of lead-covered cables, joints, &c.; Fowler, Lancaster and Co.—electric lighting plant, fittings in wrought iron, copper, &c., *spécialité* in switches and presses in porcelain, &c., dynamos and gas engines; Frictionless Engine Packing Company—electric frictionless engine packing; Hartley and Co., plating dynamo, *spécialités* in electro-plating, &c.; N. T. Henley—table with case containing coils of electric cable for electric light, &c.; General Electric Company—electric appliances; Glover and Co.—cables, wires, &c.; A. A. Goldster—electric lamps (arc and incandescent), electric light fittings, &c.; The Gülcher Electric Light and Power Company (Limited)—dynamos, motors, arc lamps, &c.; Hand and Co.—lightning conductors; Hateley and Lea—electric fittings, chandeliers, &c.; Immisch and Co.—tramcar electric motor, constant-current motors, &c.; Julien Electric Company—electric tram car; Lacombe and Co.—all forms of carbon for electric use, &c.; Laing, Wharton and Down—electric lighting, electric welding, &c.; Laurence, Paris and Scott—dynamos, motors, &c.; London Electric Wire Company—covered wires and cables for electric purposes; Muller, C. A.—electric measuring instruments manufactured by S. Schuckert (Nuremburg), electric light carbons, &c., manufactured by C. H. Schmelzer; Mayfield and Co.—special Wimshurst electric machines, electric apparatus, &c,; Nalder Brothers—reflecting and other galvanometers, resistance coils, Wheatstone bridges, &c.; Planet Electrical Engineering Company—dynamos, arc lamps, lighting, &c.; Scott and Co.—electric lighting, dynamos, switch-boards, &c.; Shippey Brothers—electric lighting, dynamos, lamps, motors, batteries, &c.; the Schanschieff Electric Battery Syndicate Company—batteries, lamps, &c.; Thonet Brothers—electric lathes, chandeliers; United Electric Engineering Company—telpherage, &c.; Woodhouse and Rawson—switches, incandescent lamps, switch-boards, motors, &c. The cages, fans, &c., of the coal mine will be worked entirely by electric motors, and the various systems of hand lighting will be shown.

REVIEWS.

Physical Memoirs, Selected and Translated from Foreign Sources under the direction of the Physical Society of London. Vol. I. Part I. (Messrs. Taylor and Francis, 1888.)

(FIRST NOTICE.)

In addition to publishing the collected memoirs of some of our leading physicists, as has already been done in the case of Wheatstone and Joule, the Council of the Physical Society decided some time ago upon issuing from time to time a series of translations of important physical Papers communicated to various foreign periodicals. There is no doubt that the series will be one of great value, and it will be something of the same character as the physical portion of "Taylor's Scientific Memoirs" which was started a good many years ago, but unfortunately could not be carried on as it was found impossible to make the undertaking a self-supporting one. The rate at which the present series will be issued will depend upon the funds at the disposal of the Society for the purpose, and as it is now increasing its numbers considerably, we trust that this rate will soon be accelerated. The present instalment consists of a selection of some of the most important of Prof. von Helmholtz's Papers bearing on the chemical relations of electric currents. The first four of these, namely, "Studies on Electric Boundary Layers" and three Papers on the "Thermo-Dynamics of Chemical Processes," have been translated by Mr. E. F. J. Love, M.A., of Mason's College, Birmingham, and the fifth and concluding Paper, entitled "Further Researches respecting the Electrolysis of Water," has been translated by Prof. S. P. Thompson. The translators' work has all through been exceedingly well done.

It is pointed out in the first of these Papers that the theory which has hitherto been held of the distribution of electricity among a system of conductors leads to the conclusion that electricity existing in equilibrium upon one or more conducting bodies forms an infinitely thin layer on their surfaces, leaving the interior portion completely free. Experimentally it is quite clear, from experiments in which an electrified conductor is allowed to discharge itself into a separate insulated conducting envelope, and its electrical condition investigated after the envelope has been removed, that this layer is really extremely thin, and that if any quantities of electricity are retained within the mass of a conductor they can only be vanishingly small. As long as it is a question only of a simple electric boundary-layer, or a conductor in contact with other conductors or insulators without any discontinuity in the value of the potential, no difficulty is presented by the supposition of a finite quantity of electricity spread out in an infinitely thin layer, and therefore of infinite volume density. For the energy of any one portion of a charge of this kind being proportional to the product of the quantity of electricity at the given point into the value of the potential at that point, remains finite. This is not the case, however, when there is a discontinuity in the potential at the surface of separation between two bodies; and in order that a difference in the value of the potential may be exhibited an electric double layer must be formed at the bounding surface. The most familiar example of such a condition of things is given by the case of two conductors in contact with an E.M.F. of contact between them. In this case there will be a positive charge upon one plate, and an equal negative charge upon the other, and if the two plates are kept in metallic contact by means of a wire, while their surfaces are made to approach each other, the accumulation of electricity upon the plates gradually increases as the distance diminishes, but always in such a manner that the product of the distance between the two plates into the density of the distribution on either always remains constant. The author calls this product the moment of the electric double layer. This moment is equal to the potential difference existing between the plates divided by 4π, and as this potential difference remains of constant magnitude, even if the plates come into the same perfect contact as that at the already existing point of connection, the moment of the electric double layer must even in this case remain constant. Sir William Thomson has pointed out that a certain definite amount of work, which he shows how to calculate, is expended in forming an electric double layer. This work may be done either mechanically, by the attractive forces between the two plates charged by contact with one another, or thermally, if the plates are brought near together on insulating stands, and then connected by means of a wire, so as to allow them to become charged. The work expended in heating the wire would, according to his formula, be infinite if the distance between the plates could be reduced to zero, and therefore the density of electrification would also become infinite. Sir W. Thomson, however, maintains that the expenditure of work for the greatest possible extension of surface of two given metals cannot exceed the mechanical equivalent of the heat developed in melting them together, as in this case their combination is more complete than would be the case if leaves however thin of the metals were simply laid one upon the other. If the leaves can be made so thin as just to receive the double layer, the maximum expenditure of work would be attained. In this way a minimum value of the distance between two leaves may be determined, and Sir W. Thomson estimates it at the thirty-millionth of a millimetre (*Nature*, March 31 and May 19, 1870). In the case of metallic electrodes in an electrolyte which cannot be decomposed by the E.M.F. employed, we have an example of molecular contact between two conductors with the possibility of a variable discontinuity of potential. There will here be an electric double layer of which the moment corresponds with the sudden change of potential existing at the time from the electrode to the fluid; and this double layer, which is set up at the surface of the electrodes, under the influence of the polarising current, must be capable of discharging itself in the depolarising current, so far as it is not dissipated by diffusion or by residual metallic conduction in the electrolyte. The force which causes this accumulation of electricity on the bounding surface of two metals in contact must—as the author pointed out in his Paper, "Ueber die Erhaltung der Kraft"—be due to different attractions of different metals for electricity. The author, therefore, assumes that for every metal there is a certain quantity, K, which expresses the amount of potential energy represented by the attraction of the metal for a positive unit of electricity at a distance which is great compared with the molecular forces; this quantity will accordingly be lost when the unit of electricity passes within the interior of the metal. It is easy to see that this hypothesis leads to the ordinary law of the electromotive series. This law only holds for bodies which conduct without electrolysis and are at the same temperature. In these, the electricity tends towards a condition of equilibrium. The maintenance of a continuous current when an electrolytic conductor is interposed, may be explained by the fact that a chemical transformation is going on in the electrolyte, and therefore the attainment of static equilibrium in impossible. The work K is done by a force which only begins to act at molecular distances, and, therefore, the change in the value of K, in passing from one metal to another in contact with it, may be supposed to take place, not suddenly, but continuously within a boundary layer with a breadth of the same order of magnitude as the sphere of action of the molecular forces. There is no reason why the force producing the work K should not exist in the case of insulators as well as of conductors, and this assumption leads to a very simple means of explaining the phenomena of frictional electricity. When two metals are separated from each other the charges remaining on them will vary greatly, as they will depend upon their relative position at the moment when the last contact occurred, but if one or both be insulated there can only be a very incomplete discharge. The author then shows by a simple calculation that very high values of the potential may be attained in this way. The calculation shows that if the insulation were perfect an E.M.F. even much smaller than that which exists between copper and zinc would be capable of giving rise to such actions as are exhibited by frictional electrical machines, and they show, moreover, that the essential requisite for success in obtaining powerful action is the complete absence of conductivity on the part of at least one of the bodies rubbed together. The result is in complete accordance with experiment. We may therefore regard friction under moderate pressure as the means of obtaining a complete and widely-extended contact between two electrically

Digitized by Google

different bodies. The author calls attention to the fact that the potential series for frictional electricity is very incompletely determined and that the relation between two bodies shows great variability even when no change in the surface in contact is perceptible. This, however, becomes comprehensible when we remember that it is only a superficial layer, perhaps not exceeding the millionth of a millimetre in thickness, which takes part in the action. This thin layer may vary without our cognizance, it may be detached by friction and electrification developed between it and the interior; or, again, as the author suggests, other charges may have left behind their residua on the insulator and have become inactive externally on account of the opposite charge of the surface. If the surface charged, however, is torn off by friction the earlier electrification may become apparent, and this would explain many of the irregularities arising in the friction of bodies which come close together in the potential series. While the rubbed bodies are close together the electric double layers are held fast by the attraction of the molecules of matter, and the value of the potential is a minimum since the opposite layers are close together. When they are separated their potential will rise rapidly and sparks may pass between the strongly-charged insulator and conductor, consisting obviously in the transport of electrified particles. The partial combination of the opposite electrifications might take place immediately behind the line of separation between the two surfaces, supposing one of them to be a sufficiently good conductor to allow of the rapid flow of electricity needed for a spark discharge. In frictional electrical machines this is prevented by attaching a strip of silk to one edge of the cushion, covering the edge of the glass disc or the surface of the cylinder for some distance from the amalgamed rubber. This silk covering stands in the same electrical relation to the glass as the amalgamed surface. The electric double layer then remains bound, in consequence of the molecular force, up to the edge of the silk where no sensible spark discharge can take place. The cushion itself must be well connected to earth in order to carry away the negative electrification, so that the rubber practically consists of a combination conducting at the beginning and insulating at the end. This springing back of the charge across the line of separation may easily be seen by removing the silk and working the machine in the dark, when a series of brush charges will be observed between the cushion and the glass which has just passed it. When the silk is in its place no discharges will be seen between its edge and the glass. In some experiments which he made, the author found that about half the electricity was lost by these discharges when the silk covering was removed. That even the best insulators possess some conductivity is shown by the residual charge of the "Leyden" jar, and by Wüllner's investigation, according to which the electrification of an insulator ultimately distributes itself exactly as on a conductor. The electric charge of the boundary layers on two insulators in contact may therefore quite possibly be produced in the same way as in metals. As the distance through which the electricity would have to be driven can be measured only by millionths of a millimetre, and the fall of potential within this space is finite, there will be a very high E.M.F., and therefore large transferences of electricity in a short time, even if the attainment of complete equilibrium requires some hours, as in the case of the residual charge. The fact that with the ordinary electric machines a unit-jar can be charged with fewer turns when the rotation is slow than when it is rapid shows that the time of passage through the cushion is not sufficient to charge the glass completely.

Issue of Provisional Orders.—Notice has been given that the Board of Trade have issued a Provisional Order under the provisions of the Electric Lighting Acts, 1882 and 1888, with a view to the same being included in a Confirmation Bill about to be introduced into Parliament, to the Kensington and Knightsbridge Electric Lighting Company and to the Chelsea Electricity Supply Company, authorising them to supply electricity for public and private purposes within certain portions of the parish of St. Mary Abbot, Kensington.

TELEPHONE COMPANIES AND THE POST OFFICE LICENSE.

The following embodies the chief features of the Draft License under which the companies carry on telephonic business by permission of the Postmaster-General:—

THIS INDENTURE made the day of , One thousand eight hundred and eighty- , between , Her Majesty's Postmaster-General (who and his successors in office for the time being are intended to be hereinafter included in the term "the Postmaster-General"), on behalf of Her Majesty of the one part, and the Company (Limited), the registered office of which is at No. (hereinafter called "the Company"), of the other part.

WHEREAS, under or by virtue of the Telegraph Acts, 1863 to 1878, and the Acts of Parliament, charters, grants, and agreements therein referred to, and of divers conveyances, awards, and assurances, executed in pursuance of the said Acts or some or one of them, the Postmaster-General has power to construct and work telegraphs, and to grant leases and licenses and enter into agreements of and with respect to telegraphs and telegraph undertakings and the working and using thereof.

AND WHEREAS the Company have been formed for the purpose amongst other things of carrying on the business of constructing, manufacturing, maintaining, working, and using telegraphs consisting of wires, telephones, and other transmitting and receiving instruments and other telegraphic apparatus and of permitting and aiding in the working and user of such telegraphs as aforesaid, and of selling and letting on hire such telegraphs as aforesaid for the purposes of such working and user as aforesaid.

AND WHEREAS by reason of the provisions of the said Acts such part of the said business of the Company as is intended to be hereby licensed cannot be carried on without the license or sanction of the Postmaster-General.

AND WHEREAS at the request of the Company and in order to enable them to carry on the said business in manner hereinafter authorised, the Postmaster-General has agreed to grant to the Company the licenses, powers, and authorities hereinafter expressed and contained for the period upon the terms and subject to the stipulations and conditions hereinafter appearing.

NOW THIS INDENTURE WITNESSETH, &c.

[Here follows an interpreting clause—1. defining, among other things, a telephone as an instrument used for transmitting or receiving spoken messages by means of electricity.]

License to Company to carry on Telephone Business.—2. The Company shall during the term of 31 years commencing on or as from the 1st day of January, One thousand eight hundred and eighty-one (determinable nevertheless as in this Indenture provided), have license and permission from the Postmaster-General (subject as heieinafter provided) to work and use telegraphs of which the transmitting and receiving instruments shall be telephones, but no other kind or description of telegraphs, for the purpose of enabling any person with whom the Company agree in that behalf, to transmit, direct from, and receive at any office to and from any other person at any other office by means of spoken words (but not otherwise), and with the aid of such telegraphs as aforesaid, telegraphic messages relating to the business or private affairs of such persons respectively, or one of them; and the Company shall have license and permission to receive from all such persons as they shall agree with as aforesaid for or in respect of the purchase or hire or maintenance or working or use of the said telegraphs or any part or parts thereof for the purpose aforesaid or for or in respect of the right or permission to transmit or receive or otherwise in respect of the transmission or receipt of such telegraphic messages as aforesaid by means of the said telegraphs such sums of money or other valuable considerations as shall be agreed upon between the Company and the said persons respectively PROVIDED ALWAYS that the term "business" used in these presents shall not be construed or held to mean or include the business of collecting receiving or delivering messages or other communications transmitted or intended for transmission by telegraph or any other business of a like kind.

Clause 3 forbids the transmission and receipt of written messages.

Clause 4 forbids the collection or delivery of telephone messages.

Clause 5 makes provision for the breach of these conditions.

Unlicensed Telegraphs not to be used for Company's Business.—6. The company shall not at any time use, or permit or suffer to be used for any of the purposes of these presents, or any of the licenses, powers, or authorities hereby granted, any telegraph of the kind or description hereby licensed, or any part of any such telegraph which has been supplied to, or has come into the possession of any person otherwise than by purchase, hire, or loan from the company, or in respect of which, or of the purchase or hire, or maintenance, or working, or user, or right of user of, or permission to use which any money or other valuable consideration has been given or agreed to be given to the company before such telegraph, or part of such telegraph, as aforesaid, was telegraphically connected with the aforesaid telegraphs of the company, or has been given or agreed to be given to any person other than the company either before or after the execution of these presents unless, and until the company shall have given notice in writing to the Postmaster-General of their desire to use such

Digitized by Google

telegraph, or part of such telegraph, as aforesaid, three clear days at least before the user thereof, and until such notice has been given no such telegraph or part of such telegraph, shall be deemed to be within the license and permission granted by these presents, and from and after the expiration of such notice, the company may work and use such telegraph or part of such telegraph as aforesaid, in the same manner as any other telegraph or part of any telegraph hereby licensed, subject on the part of the company to the payment of the royalty hereinafter mentioned in respect thereof, and to the observance and performance of the several covenants and conditions herein contained affecting the same.

Royalties.—7. In addition to all other moneys which may become payable to the Postmaster-General under these presents, the company shall pay to the Postmaster-General the following moneys hereinafter called royalties (that is to say)—

(1) The company shall pay to the Postmaster-General a royalty equal to 10 per cent. of the gross amount of every sum of money paid or payable by any person to or on behalf of the company, for or in respect of the purchase, or hire, or maintenance, or working, or user, or right of user of, or permission to use any telegraph or telegraphs of the kind or description hereby licensed, or any part or parts of such telegraph or telegraphs or for, or in respect of the user, or right of user of, or permission to use any office or part of an office occupied by the Company or otherwise in respect of telegraphic messages transmitted by means of any such telegraph or telegraphs, or otherwise howsoever in relation to any such telegraph or telegraphs, or any part or parts thereof, and whether such sum of money be a gross sum or be payable periodically or by instalments, and every such royalty shall become due so soon as the sum of money in respect of which it is payable or by the amount of which it is regulated shall be paid or shall, by virtue of any express or implied contract or otherwise, be payable whichever event shall first happen.

(2.) In case any person should give to or confer upon the Company any valuable consideration or benefit (not being money or a contract solely for the payment of money) for, or in respect of, the purchase, or hire, or maintenance, or working, or user, or right of user of, or permission to use, any such telegraph or telegraphs, or any part or parts thereof, or for or in respect of the user, or right of user of, or permission to use, any office or part of any office occupied by the Company either solely or jointly or otherwise in respect of telegraphic messages transmitted or received by means of any such telegraph or telegraphs or otherwise howsoever in relation to any such telegraph or telegraphs, or any part or parts thereof, the Company shall pay to the Postmaster-General a royalty equal to 10 per cent. of the value in money of such consideration or benefit, and for the purpose of estimating the amount of such last-mentioned royalty the value in money of such consideration or benefit shall be determined by the certificate of such officer of the Post Office as the Postmaster-General shall appoint for that purpose, or in case of dispute by arbitration as hereinafter provided, and such royalty shall be payable and paid at such time or times and by such instalments and generally in such manner as the Postmaster-General shall appoint, and shall be payable in addition to such royalty or royalties (if any) as shall be payable in respect of such person under the stipulations hereinbefore contained.

(3.) In case any sum of money be paid, or payable to, or other valuable consideration or benefit be given to or conferred upon the company by any person or persons for, or in respect of the purchase, or hire or maintenance, or working or user, or right of user of, or permission to use any telegraph maintained or used solely for the transmission of telegrams which are by law excepted from the exclusive privileges of the Postmaster-General (hereinafter for brevity styled a "private telegraph") in addition to any sum of money paid or payable or other valuable consideration given to or conferred upon the company by the same person or persons for or in respect of the purchase or hire or maintenance or working or user or right of user of or permission to use any telegraph of the kind or description hereby licensed the Postmaster-General may at his option apportion such sums or other valuable considerations respectively either in whole or in part between the said private telegraph and such other telegraph as aforesaid in such manner or in such proportions as he may deem fit and proper, and thereupon such sums or other valuable considerations respectively as he shall apportion accordingly shall as between the company and the Postmaster-General for the purposes of these presents be deemed to be the sums or valuable considerations respectively paid or given by such persons as aforesaid in relation to such private telegraph and such other telegraph as aforesaid respectively in lieu of the sums or valuable considerations actually paid or given by such persons in relation to such telegraphs respectively.

(4.) In case the Company should, as hereinbefore provided, use or permit suffer to be used for any of the purposes of these presents, or any of the licenses, powers, or authorities hereby granted, any telegraph of the kind or description hereby licensed, or any part of any such telegraph which has been supplied to, or has come into the possession of, any person otherwise than by purchase, hire, or loan from the Company, or in respect of which, or of the purchase, or hire, or maintenance, or working, or user, or right of user of, or permission to use which any money or other valuable consideration has been given or agreed to be given to the Company before such telegraph or part of such telegraph as aforesaid was telegraphically connected with the aforesaid telegraphs of the Company, or has been given or agreed to be given to any person other than the Company either before or after the execution of these presents, the Company shall pay to the Postmaster-General such a royalty in respect thereof as under all the circumstances of the case shall be fair and reasonable, and the amount thereof shall be determined by the certificate of such officer of the Post-office as the Postmaster-General shall appoint for that purpose, or in case of dispute by arbitration, as hereinafter provided, and shall be payable and paid at such time or times, and by such instalment and generally in such manner as the Postmaster-General shall appoint

(5.) Nothing herein contained shall entitle the Postmaster-General to receive any royalties from the company on any money or other valuable consideration received by the company on the sale of any telegraph or telegraphs which the company after such sale do not work or use under this license, it being the intention of these presents that all royalties payable to the Postmaster-General in respect of any such telegraph or telegraphs shall be paid by the person working or using the same, provided always that the company shall seven days at least before any such sale of any such telegraph or telegraphs as last aforesaid deliver a notice in writing of such intended sale at the General Post Office in London, and such notice shall contain the name, address, and occupation of the intended purchaser or purchasers of such telegraph or telegraphs, and also full particulars of the offices intended to be connected by means thereof.

Clauses 8 and 9 deal with the accounts which are to be kept by the companies and furnished to the Postmaster-General quarterly.

Payments to be made Quarterly.—10. The Company shall pay to the Postmaster-General within six weeks after the 31st day of March, the 30th day of June, the 30th day of September, and the 31st day of December in every year the amount or amounts which shall be due to the Postmaster-General in respect of the preceding quarter of a year.

Power to Postmaster-General to inspect Telegraphs at all offices.—11. The Postmaster-General and his engineers and agents may from time to time, and at all reasonable times enter upon all or any office or offices in the possession or occupation of the company either solely or jointly with any other person or persons respectively for the purpose of inspecting and may inspect the telephones and other telegraphic instruments and appliances fixed or being in such places respectively, and the working and user of such telegraphs respectively, and the company shall from time to time upon the request of the Postmaster-General procure from any person permitted by them to use the said telegraphs at any other office or offices which may be occupied by them either solely or jointly with any other person, his consent to such entry and inspection so far as regards such office or offices of such person and the telephones and other telegraphic instruments and appliances fixed or being in such office or offices.

License not to be assigned.—12. The company shall not assign, underlet, or otherwise dispose of the powers or authorities hereby granted or any of such powers or authorities without the consent in writing of the Postmaster-General.

Company's Telegraphs not to interfere with Postal Telegraphs.—13. All telegraph posts, wires, and telegraphic appliances used or intended to be used as part of or in connection with the telegraphs of the company, shall be so erected, fixed, placed, and used as not either directly or by reason of the working or user thereof to interfere with the efficient or convenient maintenance, working, or user of any telegraph posts, wires, or telegraphic appliances of the Postmaster-General, which may from time to time exist, or which it is probable that the Postmaster-General may have occasion to erect, place, fix, or use, or to expose any such posts, wires, or appliances to risk of damage, or to risk of interference with the efficient or convenient working or user thereof.
